Aspects of Termination

What the talk is about:

- $\checkmark\,$ foundational approach to termination
- $\checkmark\,$ types and semantics
- $\checkmark\,$ compositional termination
- \checkmark communicating termination (across function/module boundaries)

🗸 MiniAgda

What the talk is not about:

- × smart termination orders
- × automatic termination inference

Well-typed programs don't go wrong

- Desired: absence of run-time errors (don't go wrong).
- Property not compositional!
- If f and a don't go wrong, f a might still!
- Milner: introduce types to "strengthen induction hypothesis".
- Polymorphic types allow to abstract out code $t[u] \rightsquigarrow \text{let } x = u \text{ in } t$.
- Types make error-freeness compositional!

Well-typed programs terminate

- Desired: termination (or stream productivity).
- Termination is not compositional!
- If f and a terminate, f a might still diverge! (E.g. $f = a = \lambda x. x x$)
- Welltyped programs terminate!?
 - ✓ Simply-typed lambda-calculus
 - ✓ Polymorphic lambda-calculus (System F)
 - X Haskell (has recursion)
 - X Agda, Coq (have separate termination checking)
- What is the problem with a separate termination check?

A simple, terminating function

Picks every other element from a list.

```
fun every0ther : List A \rightarrow List A
{ every0ther nil = nil
; every0ther (cons a nil) = nil
; every0ther (cons a (cons a' as)) = cons a (every0ther as)
}
```

- Terminates, since as < cons a (cons a' as).
- Abstract out 0-1-many case distinction:

イロト 不得下 イヨト イヨト 二日

Abstractions not supported

• Function using combinator zeroOneMany.

```
fun every0ther : List A \rightarrow List A
{ every0ther l = zero0neMany l
    nil
    (\lambda a \rightarrow nil)
    (\lambda a a' as \rightarrow cons a (every0ther as))
}
```

- Terminating? Relation between as and 1 lost.
- Inlining zeroOneMany?
 - X Bad performance of checker.
 - X Source code might not be available.
- Trouble with abstraction? Types to the rescue!

Type-based termination

- Refine types: List A i contains lists up to length i.
- \bullet A precise type with bounded universal [j $\,<\,i$] $\,\rightarrow\,\ldots$

• Relation between as : List A j and l : List A i tracked by types!

イロト 不得下 イヨト イヨト 二日

Summary: Type-based termination

- Type-based termination is compositional.
- Need only type, not code, of used functions.
- Module-wise termination check.
- Little overhead to classic type checking.
- Strength depends on language of sizes.
- Here: foundational concept of size...

Sizes as iteration stages

- Inductive types are least fixed points.
- List $A \cong \mu F$ with $F X = \top + A \times X$.
- Approximating the fixed-point from below:

- List $A i = \mu^i F$ gives lists of length < i.
- For monotone *F* it holds that

$$\mu^{\alpha}F = \bigcup_{\beta < \alpha}F(\mu^{\beta}F)$$

(日) (同) (三) (三)

Recursion principle

• Transfinite recursion on sizes:

$$\frac{f:\forall i. A i \to A(i+1)}{\text{fix } f:\forall i. A i}$$

- Base case: $A 0 = \top$.
- Limit case: $\bigcap_{\alpha < \lambda} A \alpha \subseteq A \lambda$.
- Typical use: $Ai = \mu^i F \rightarrow Ci$.
- Basis of almost all work on type-based termination.
- Can we avoid the side conditions?

イロト イ団ト イヨト イヨト 三日

Inflationary least fixed points

• Take proven equation as definition of $\mu^{\alpha} F$!

$$\mu^{\alpha}F = \bigcup_{\beta < \alpha}F(\mu^{\beta}F)$$

- Irrelevant: Reaches fixed point also for non-monotone F.
- Relevant: No case on 0, $_-+1$, and λ (limit).
- Sizes α, β need not be classical ordinals.
- Allows recursive definition of inductive types:

List A i = [j < i] & Maybe (A & List A j)

Bounded existential [j < i] & \ldots and cartesian product A & B.

イロト 人間ト イヨト イヨト

Recursion principle

• Well-founded recursion on sizes:

 $\frac{f:\forall i. (\forall j < i. Aj) \to Ai}{\mathsf{fix}\, f:\forall i. Ai}$

- No conditions on A!
- Definable in MiniAgda:

イロト イポト イヨト イヨト 二日

Inflationary greatest fixed points

• Coinductive types are greatest fixed points.

$$\nu^{\alpha}F = \bigcap_{\beta < \alpha}F\left(\nu^{\beta}F\right)$$

- Stream $A i = \nu^i F$ with $F X = A \times X$
- Stream A i are streams of depth i.
- Can be unrolled safely up to *i* times.

Stream A i = [j < i] \rightarrow A & Stream A j

(日) (同) (三) (三)

Programming streams

• Deconstructing and constructing streams:

```
Stream A i = [j < i] \rightarrow A & Stream A j
```

```
let tail [i : Size] (s : Stream A (i+1)) : Stream A i
= case (s i) { (a, as) \rightarrow as }
```

```
cofun repeat (a : A) [i : Size] \rightarrow Stream A i { repeat a i = \lambdaj \rightarrow (a, repeat a j) }
```

• **repeat** is productive because j < i.

The famous Fibonacci stream

```
Zipping two streams with function f.
cofun zipWith : [i : Size] → (A → B → C) →
Stream A i → Stream B i → Stream C i
{ zipWith i f sa sb = λj →
case (sa j, sb j)
{ ((a, as), (b, bs)) → (f a b, zipWith j f as bs)
}
Fibonacci stream 0,1,1,2,3,5,8,13,...
```

}

Mixed Induction-Coinduction

- Classification of recursive data types
 - Inductive μ (lists, trees, Brouwer ordinals)
 - Coinductive ν (streams, processes)
 - Coinductive-inductive $\nu\mu$ (stream processors)
 - Other mixes...
- How do mixed types fit into our framework?

Stream processors

 Stream processors [Ghani, Hancock, Patterson] code continuous maps on streams.

```
data SP a b = Get (a \rightarrow SP a b)
| Put b (SP a b)
```

- Get: We can either read an a from the input stream and enter a new state depending on a, or
- Put: write a b on the output stream and enter a new state.
- run executes a SP.

run :: SP a b \rightarrow [a] \rightarrow [b] run (Get f) (a : as) = run (f a) as run (Put b sp) as = b : run sp as

|▲冊 ▶ ▲ 臣 ▶ ▲ 臣 ▶ □ 臣 □ - のへ(?)

Stream processors (cont.)

• Continuity: An output must appear after finite input.

- X No infinite succession of Gets.
- \checkmark Infinite sequence of Puts possible.

$$\frac{f: A \to \mathsf{SP}}{\mathsf{get} \ f: \mathsf{SP}} < \omega \qquad \frac{b: B \quad sp: \mathsf{SP}}{\mathsf{put} \ b \ sp: \mathsf{SP}} \leq \omega$$

• Model SP by nesting μ into ν .

$$SP = \nu X.\mu Y. (A \rightarrow Y) \times (B \times X)$$

• We can restart getting after a put.

$$SP = \mu Y. (A \rightarrow Y) \times (B \times SP)$$

イロト イポト イヨト イヨト

Lexicographic recursion

• Nested inflationary fixed-points:

 $\mathsf{SP} \ \alpha \ \beta = \bigcap_{\alpha' < \alpha} \bigcup_{\beta' < \beta} (A \to \mathsf{SP} \ \alpha \ \beta') + (B \times \mathsf{SP} \ \alpha' \ \infty)$

- $\bullet \infty$ is closure ordinal.
- Type defined by lexicographic recursion.
- Pushing quantifiers in:

$$\mathsf{SP} \ \alpha \ \beta = (\mathsf{A} \to \bigcup_{\beta' < \beta} \mathsf{SP} \ \alpha \ \beta') + (\mathsf{B} \times \bigcap_{\alpha' < \alpha} \mathsf{SP} \ \alpha' \ \infty)$$

- Coinductive occurrence prefixed by universal/existential.
- Sizing scheme ((α', ∞) vs. (α, β')) represents nesting $\nu \mu$.

Stream Processors in MiniAgda

• Type def. and pattern synonyms:

• run defined by lexicographic recursion over *i*, *j*.

Wrapping up

- Type-based termination is compositional and local.
- Inflationary iteration provides simple foundation.
- (Co)induction is replaced by well-founded recursion on size.
- Mixed types just fall in our lap.

(日) (同) (三) (三)

There is more to it

- Size language has $0, +1, \infty, \max$ and possibly +.
- Bounded quantification induces subtyping, e.g.:

List $Ai = \bigcup_{j < i} (\top + A \times \text{List } Aj)$ covariant in A and i

- Size is tree height/depth. Other size assignments!?
- Termination measures are lexicographic products of sizes. What else do we need?
- Most sizes are inferable.
 Integrate size solving with higher-order unification!

Termination and Metavariables

- Agda: a dependently typed language with interactive proof/program development.
- Metavariables stand for missing code
- ... filled in by Agda or the user.
- Only well-typed solutions accepted.
- Easy, because type checking is local.
- Global properties like positivity and termination not checked.
- Agda refuses to solve recursive metas; solution might be diverging.
 Integrate all static checks into type system!
 - \implies Smaller implementation, no corner cases, orthogonality.
