Abstract
We define a block based matrix representation in Agda and lift various algebraic structures (semi-near-rings, semi-rings and closed semi-rings) to matrices in order to verify algorithms that can be implemented using the closure operation in a semi-ring.

Categories and Subject Descriptors D.1.1 [Programming Techniques]: Applicative (Functional) Programming; F.3.1 [Logics and Meanings of Programs]: Specifying and Verifying and Reasoning about Programs

Keywords Dependent types, Linear Algebra

1. Introduction
Bernardy and Jansson [2016] used a recursive block formulation of matrices to certify Valiant’s parsing algorithm (Valiant [1975]). Their matrix formulation was restricted to matrices of size $2^\infty \times 2^\infty$ and this work extends the matrix formulation to allow for all sizes of matrices to certify Valiant’s parsing algorithm (Valiant [1975]).

Development Structure To structure the formal development we define a hierarchy of ring structures as Agda records: A semi-nearring for some type $s$ needs an equivalence relation $\simeq$, a distinguished element $0_s$ and operations addition $+_s$ and multiplication $\cdot_s$. Our semi-near-ring requires that $0_s$ and $+_s$ form a commutative monoid (i.e. $+_s$ commutes and $0_s$ is the left and right identity of $+_s$), $0_s$ is the left and right zero of $+_s$, $+_s$ is idempotent $(\forall x \rightarrow x \cdot x \simeq x)$ and $\cdot_s$ distributes over $+_s$.

For the semi-ring we extend the semi-near-ring with another distinguished element $1_s$ and proofs that $\cdot_s$ is associative and that $1_s$ is the left and right identity of $\cdot_s$.

Finally we extend the semi-ring with an operation closure that computes the Kleene star (reflexive and transitive closure) of an element of the semi-ring ($c$ is the closure of $w$ if $c \simeq w \cdot c$ holds), we denote the closure of $w$ with $w^\ast$.

We use two examples of semi-rings with transitive closure: (1) the Booleans with disjunction as addition, conjunction as multiplication and the closure being true; and (2) the natural numbers ($\mathbb{N}$) extended with an element $\infty$, we let $0_s = \infty$, $1_s = 0$, min plays the role of $+_s$, addition of natural numbers the role of $\cdot_s$ and the closure is $\emptyset$.

2. Shapes, Matrices and Closure
To represent the dimensions of matrices we use a type of non-empty binary trees:

\begin{align*}
\text{data} \quad & \text{Shape} : \text{Set} \\
L & : \text{Shape} \\
B & : \text{Shape} \rightarrow \text{Shape} \rightarrow \text{Shape}
\end{align*}

This representation follows the structure of the (block) matrix representation more closely than natural numbers and we can easily compute the corresponding natural number:

$\text{toNat} : \text{Shape} \rightarrow \mathbb{N}$

$\text{toNat} L = 1$

$\text{toNat} (B \ l \ r) = \text{toNat} l + \text{toNat} r$

while the other direction is slightly more complicated because we want a somewhat balanced tree and we have no representation for $\emptyset$.

Matrices are parametrised by the type of elements they contain and indexed by a Shape for each dimension. We use a datatipe $M$ with four constructors: One, Row, Col, and Q. The first One lifts an element into a 1-by-1 matrix:

\begin{align*}
\text{data} \quad & M (\ a : \text{Set}) : (\text{rows} \ : \text{Shape}) \rightarrow \text{Set} \\
\text{One} & : \ a \rightarrow \ M\ a\ L\ L
\end{align*}

Row and column matrices are built from smaller matrices which are either 1-by-1 matrices or further row or column matrices:

$\text{Row} \ : \ \{c_1\ c_2 : \text{Shape}\} \rightarrow \ M\ a\ L\ c_1 \rightarrow \ M\ a\ L\ c_2 \rightarrow \ M\ a\ L\ (B\ c_1\ c_2)$

$\text{Col} \ : \ \{r_1\ r_2 : \text{Shape}\} \rightarrow \ M\ a\ r_1\ L \rightarrow \ M\ a\ r_2\ L \rightarrow \ M\ a\ (B\ r_1\ r_2)\ L$

and matrices of other shapes are built from $2 \times 2$ smaller matrices:

$\text{Q} \ : \ \{r_1\ r_2\ c_1\ c_2 : \text{Shape}\} \rightarrow \ M\ a\ r_1\ c_1 \rightarrow \ M\ a\ r_1\ c_2 \rightarrow \ M\ a\ r_2\ c_1 \rightarrow \ M\ a\ r_2\ c_2 \rightarrow \ M\ a\ (B\ r_1\ r_2)\ (B\ c_1\ c_2)$

This matrix representation allows us to lift a semi-ring to a semi-ring of matrices and allows for intuitive definitions of matrix operations and proofs that the lifted structures satisfy the laws of our semi-rings.

To give a taste of the formal development we include one simple proof and a fragment of the larger development. The proof examples show how we use the Agda standard library’s equational reasoning framework to make the proofs easier to write and read, this tool is used heavily throughout the development. To prove that the zero matrix is the right identity of addition we use commutativity of...
We have presented an algebraic structure useful for (block) matrix computations and implemented and proved correctness of reflexive transitive closure. Compared to (Bernardy and Jansson 2016), our implementation handles arbitrary matrix dimensions but is restricted to semi-rings. Future work would be to extend the proof to cover both arbitrary dimensions and the more general semi-near-ring structure which would allow parallel parsing as an application.

The second proof example (in Fig. 1) shows how we use local modules (lemma1) and abbreviations (X) to make the proof terms resemble hand-written proofs.

**Transitive Closure** [Lehmann 1977] presents a definition of the closure on square matrices, \[ A^* = I + A \cdot A^* \]. Given a square matrix

\[
A = \begin{pmatrix}
A_{11} & A_{12} \\
A_{21} & A_{22}
\end{pmatrix}
\]

the transitive closure of \( A \) is defined inductively as

\[
A^* = \begin{pmatrix}
A_{11} & A_{12} \cdot \Delta^* \cdot A_{21} & A_{11} \cdot A_{12} \cdot \Delta^* \\
\Delta^* \cdot A_{21} & A_{11}
\end{pmatrix}
\]

where \( \Delta = A_{22} + A_{21} \cdot A_{11} \cdot A_{12} \) and the base case is the 1-by-1 matrix where we use the transitive closure of the element of the matrix: \( A^* = A^* \).

We have encoded this definition of closure in Agda and implemented a constructive correctness proof using structural induction and equational reasoning. The full development of around 2500 lines of literate Agda code (including this abstract) is available on GitHub ([https://github.com/DSLsofMath/FLABloS](https://github.com/DSLsofMath/FLABloS)).

**Example: Graph Reachability** Using this definition of transitive closure of matrices instantiated with the boolean semi-ring defined above we get an implementation of a graph reachability algorithm. If we have a graph (Fig. 2a) and its adjacency matrix (as below) we can find all reachable nodes (Fig. 2b) by computing the transitive closure of the adjacency matrix.

\[
\begin{pmatrix}
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 \\
0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0
\end{pmatrix} \quad \Rightarrow \quad \begin{pmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 1 & 1 & 0 \\
0 & 0 & 0 & 1
\end{pmatrix}
\]
