## Modelling \& Datatypes

## Modelling Data

- A big part of designing software is modelling the data in an appropriate way
- Numbers are not good for this!
- We model the data by defining new types

## Modelling a Card Game

- Every card has a suit

- Model by a new type:

## Printing Values

Investigating the new type

## The Colours of Cards

- Each suit has a colour - red or black
- Model colours by a type
data Colour $=$ Black | Red
deriving Show
- Define functions by pattern matching

| $\begin{aligned} & \text { colour :: Suit -> Colour } \\ & \text { colour Spades }=\text { Black } \end{aligned}$ | Main> colour Hearts Red |
| :---: | :---: |
| colour Hearts = Red |  |
| $\begin{aligned} \text { colour Diamonds } & =\text { Red } \\ \text { colour Clubs } & =\text { Black } \end{aligned}$ | One equation per value |

## The Ranks of Cards

- Cards have ranks: 2..10, J, Q, K, A
- Model by a new type

| data Rank = Numeric Integer \| Jack | Queen | King | Ace <br> deriving Show |
| :--- | :---: |
| Main> :i Numeric <br> Numeric : : Integer $->$ Rank <br> Main> Numeric 3 <br> an Integer |
| Numeric 3 |

Rank Beats Rank

Rank Beats Rank

```
rankBeats :: Rank -> Rank -> Bool
rankBeats _ Ace = False
rankBeats Ace _ = True
rankBeats _ King = False
rankBeats King _ = True
rankBeats _ Queen = False
rankBeats Queen _ = True
rankBeats _ Jack = False
rankBeats Jack _ = True
```

Rank Beats Rank

Rank Beats Rank

Rank Beats Rank

## Examples

> Main> rankBeats Jack (Numeric 7 )
> True
> Main> rankBeats (Numeric 10) Queen
> False

Further reading exercise: possible to make a much simpler definition by getting Haskell to derive the ordering relations $<$, <= etc. between cards.

- Find out more about "deriving Ord"...

## QuickCheck Generators

- Test data is chosen by a test data generator
- Writing generators we leave for the future

## Modelling a Card

- A Card has both a Rank and a Suit

```
data Card = Card Rank Suit
    deriving Show
```

- Define functions to inspect both

```
rank :: Card -> Rank
rank (Card r s) = r
suit :: Card -> Suit
suit (Card r s) = s
```

## A Property

- Either a beats b or b beats a

```
prop_rankBeats a b = rankBeats a b | rankBeats b a
```

Main> quickCheck prop_rankBeats ERROR - Cannot infer instance
*** Instance : Arbitrary Rank
*** Expression : quickCheck prop_rankBeats

QuickCheck doesn't know how to choose an arbitrary Rank!

## Testing the Property

```
prop_rankBeats a b = rankBeats a b || rankBeats b a
```

Main> quickCheck prop_rankBeats
Falsifiable, after 9 tests:
King
King Provided they're not equal
prop_rankBeats $\mathrm{a} \mathrm{b}=\mathrm{a} /=\mathrm{b}=\Rightarrow$ rankBeats $\mathrm{a} \mathrm{b} \|$ rankBeats b a
data Rank = Numeric Integer | Jack | Queen | King | Ace deriving (Show, Eq) Define == for ranks

## A Useful Abbreviation

- The previous type and function definitions can be written in an equivalent abbreviated form:

[^0]
## When does one card beat another?

- When both cards have the same suit, and the rank is higher
cardBeats :: Card -> Card -> Bool cardBeats c d
| suit $c==$ suit $d=\operatorname{rankBeats}(r a n k c)$ (rank d)
| otherwise = False
data Suit $=$ Spades $\mid$ Hearts | Diamonds | Clubs deriving (Show, Eq)

## Modelling a Hand of Cards

- A hand may contain any number of cards from zero up!

- The solution is... recursion!

## When can a hand beat a card?

- An empty hand beats nothing
- A non-empty hand can beat a card if the first card can, or the rest of the hand can!

```
handBeats :: Hand -> Card -> Bool
handBeats Empty card = False
handBeats (Add c h) card =
    cardBeats c card || handBeats h card
```

- A recursive function!

## When does one card beat another?

- When both cards have the same suit, and the rank is higher

```
cardBeats :: Card -> Card -> Bool
```

cardBeats :: Card -> Card -> Bool
cardBeats c d = suit c == suit d
cardBeats c d = suit c == suit d
\&\& rankBeats (rank c) (rank d)

```
    && rankBeats (rank c) (rank d)
```

## Modelling a Hand of Cards

- A hand may contain any number of cards from zero up!
- A hand may be empty
- It may consist of a first card and the rest
- The rest is another hand of cards!

## Trickier Example:

Choose a card to play

- Given
- Card to beat
- The hand
- Beat the card if possible!

## Strategy

- If the hand is only one card, play it
- If there is a choice,
- Select the best card from the rest of the hand
- Choose between it and the first card
- Principles
- Follow suit if possible
- Play lowest winning card if possible
- Play lowest losing card otherwise

## Properties of chooseCard

- Complicated code with great potential for errors!
- Possible properties:
- chooseCard returns a card from the hand ("no cards up the sleeve")
- chooseCard follows suit if possible ("no cheating")
- chooseCard always wins if possible

## What Did We Learn?

- Modelling the problem using datatypes with components
- Using recursive datatypes to model things of varying size
- Using recursive functions to manipulate recursive datatypes
- Writing properties of more complex algorithms

## The Code

    | suit \(c==s u i t\) beat \&\& suit \(c^{\prime} /=\) suit beat \(=c\)
    | suit \(c /=\) suit beat \(\& \&\) suit \(c^{\prime}==s u i t\) beat \(=c^{\prime}\)
    | rankBeats (rank c) (rank c') = c'
    | otherwise = \(c\)
    where c' = chooseCard beat rest
    
## Testing chooseCard

```
prop_chooseCardWinsIfPossible c h =
    h/=Empty ==>
        handBeats h c
        ==
        cardBeats (chooseCard c h) c
```

Main> quickCheck prop_chooseCardWinsIfPossible Falsifiable, after 3 tests:
Card\{rank=Numeric 8,suit=Diamonds\}
Add Card\{rank=Numeric 4,suit=Diamonds\} (Add
Card\{rank=Numeric 10,suit=Spades\} Empty)

## What went wrong?

## Reminder: Modelling a Hand

- A Hand is either:
- An empty hand
- Formed by adding a card to a smaller hand
data Hand = Empty | Add Card Hand deriving Show
- Discarding the first card:

```
discard :: Hand -> Hand
discard (Add ch) = h
```

## Lists: recap

## Lists

-- how they work

- Can represent $0,1,2, \ldots$ things - [], [3], ["apa","katt","val","hund"]
- They all have the same type - [1,3,True,"apa"] is not allowed
- The order matters - [1,2,3]/= [3,1,2]
- Syntax
$-5:(6:(3:[]))=5: 6: 3:[]==[5,6,3]$
- "apa" == ['a','p','a']

## Can we define Lists as a

 datatype?data List = Empty | Add ?? List

- Our attempt at a "home made" list is either:
- An empty list
- Formed by adding an element to a smaller list
- What to put on the place of the ??

## Lists

data List a = Empty $\mid$ Add a (List a)

- Empty :: List Integer
- Empty :: List Bool
- Empty :: List String
- ...

## More on Types

- Functions can have "general" types:
- polymorphism
- reverse :: [a] -> [a]
$-(++)::[a]->[a]->[a]$
- Sometimes, these types can be restricted
- Ord a => ... for comparisons (<, <=, >, >=, ...)
- Eq a => ... for equality (==, /=)
- Num a => ... for numeric operations (+, -, *, ...)

## Do's and Don'ts

## Do's and Don'ts

## Do's and Don'ts

## Writing Code

- Beautiful code
- readable
- not overly complicated
- no repetitions
- no "junk" left
- For
- you
- other people

[^0]:    data Card = Card \{rank :: Rank, suit :: Suit\} deriving Show
