CHALMERS UNIVERSITY OF TECHNOLOGY

CHALMERS

Department of Computer Science
and Engineering

OUTLINE OF LECTURE.

- Dependability and its attributes
- Security (and its aspects)
- An integrated system model
- A biological analogy
- The time aspect
- A few observations
- Conclusions

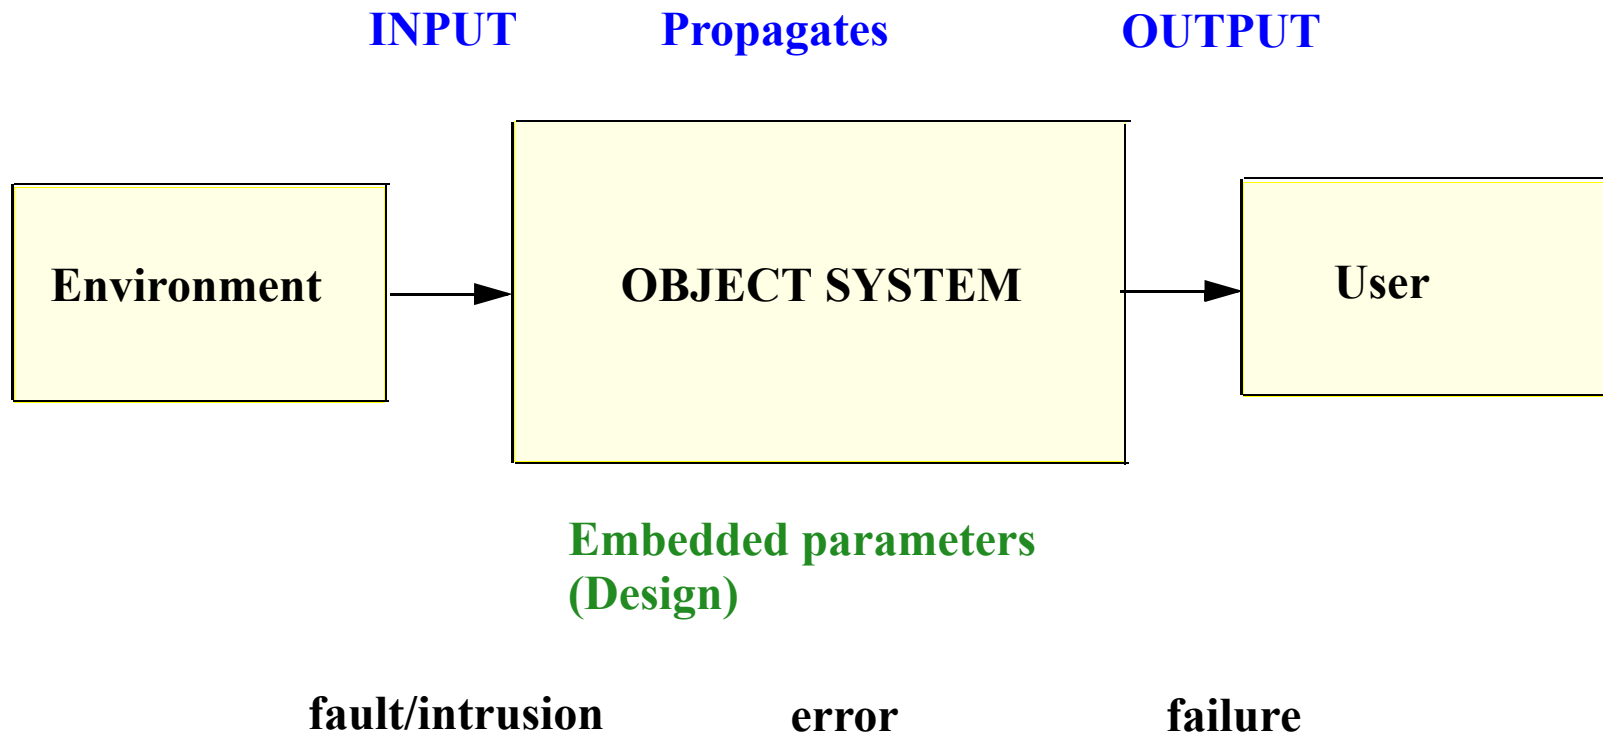

GOAL OF LECTURE.

The goal of this lecture is to:

- answer the question: “What *is* SECURITY?”
- present a **conceptual model** of dependability and security, including a suggested terminology. Thus, dependability and security represent different aspects of **a common meta-concept**.
- clarify that **security is multi-faceted** and can not be treated as a clear-cut atomic concept.
- the conceptual model is aimed to facilitate metrication of **security/dependability**

All in all: **to give a profound understanding of the security/dependability area.**

A VERY BASIC SYSTEM MODEL

DEPENDABILITY and its attributes

DEPENDABILITY ATTRIBUTES

Relation to the Dependability area:

DEPENDABILITY
ATTRIBUTES

Reliability **Availability** Safety Maintainability **Confidentiality** **Integrity**

“CIA” = **SECURITY**

DEPENDABILITY

- is a general, “umbrella” concept
- is not mathematically well-defined
- denotes the research area:
Dependable Computing

DEFINITION OF RELIABILITY

- **RELIABILITY** (“*continuity of service*”)

The reliability $R(t)$ of a system SYS can be expressed as:

$$R(t) = \text{Prob} (\text{SYS is fully functioning in } [0,t])$$

A metric for reliability $R(t)$ is MTTF, the Mean Time To Failure

$$\text{MTTF} = \int_0^{\infty} R(t) dt = \frac{1}{\lambda}, \text{ where } \lambda \text{ is the constant}$$

failure rate. MTTF is normally expressed in *hours*

DEFINITION OF AVAILABILITY

- **AVAILABILITY** (*“readiness for usage”*
- incorporates maintainability (repair))

The availability $A(t)$ of a system SYS can be expressed as:

$$A(t) = \text{Prob} (\text{SYS is fully functioning at time } t)$$

A metric for the average, steady-state availability

is $A(\infty) = \frac{MTTF}{MTTF + MTTR}$, where

$$MTTR = \frac{1}{\mu}, \text{ where } \mu \text{ is the constant repair rate.}$$

$A(\infty)$ is normally expressed in %.

- SAFETY (*“avoidance of catastrophic consequences on the environment”*)

The Safety $S(t)$ of a system SYS can be expressed as:
 $S(t) = \text{Prob} (\text{SYS is fully functioning or has failed in a manner that does cause no harm in } [0,t])$

A metric for safety $S(t)$ is MTTCF, the Mean Time To Critical Failure, defined similarly to MTTF and normally expressed in *hours*.

- SECURITY (*“prevention of unauthorized access and/or handling”*)

A system is considered Secure if it is can protect itself against intrusions

There is no mathematical or formal definition of the Security of a system.

There are no real metrics for security. Instead, there are a number of informal and/or subjective assessments or rankings.

Security is normally defined by its three aspects: confidentiality, integrity and availability (the “CIA”)

SECURITY ASPECTS

ITSEC:

INFORMATION SECURITY

Confidentiality
Sekretess

prevention of the
unauthorized dis-
closure of information

Integrity
Integritet

prevention of the
unauthorized modifi-
cation of information

Availability
Tillgänglighet

prevention of the
unauthorized withholding
of information or resources

AN INTEGRATED SYSTEM MODEL

BEHAVIOURAL
DEPENDABILITY
ATTRIBUTES

Reliability **Availability** Safety Maintainability **Confidentiality** **Integrity**

“other” characteristic

protective characteristic

AN INTERPRETATION OF TRADITIONAL DEFINITION OF SECURITY

Information security
Datasäkerhet

Confidentiality
Sekretess

prevention of the *unauthorized* disclosure of information

Integrity
Integritet

prevention of the *unauthorized* modification of information

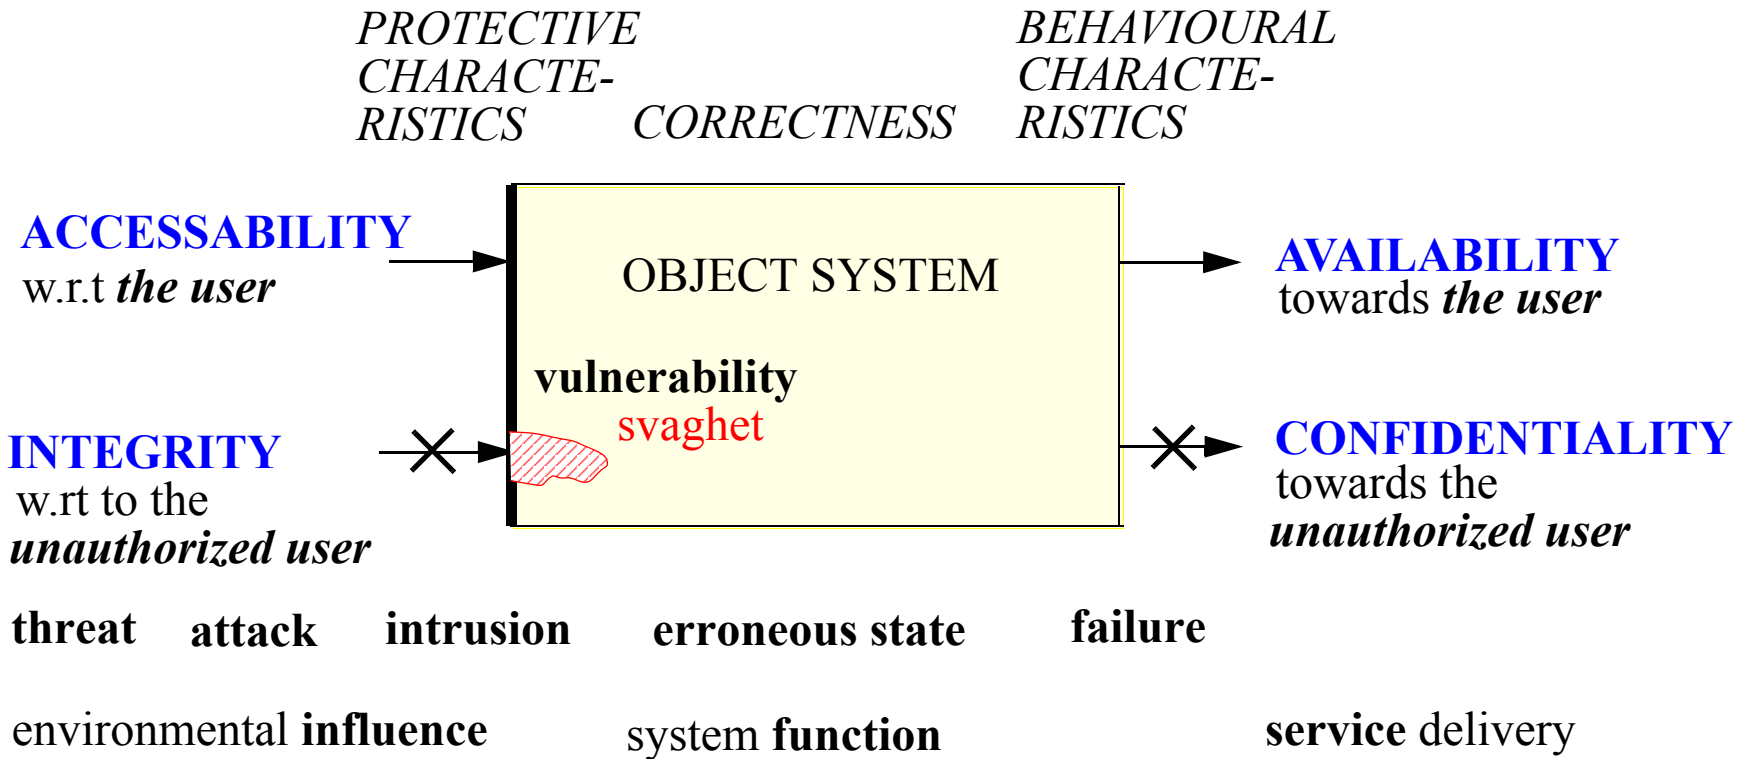

Availability (“CIA”)
Tillgänglighet

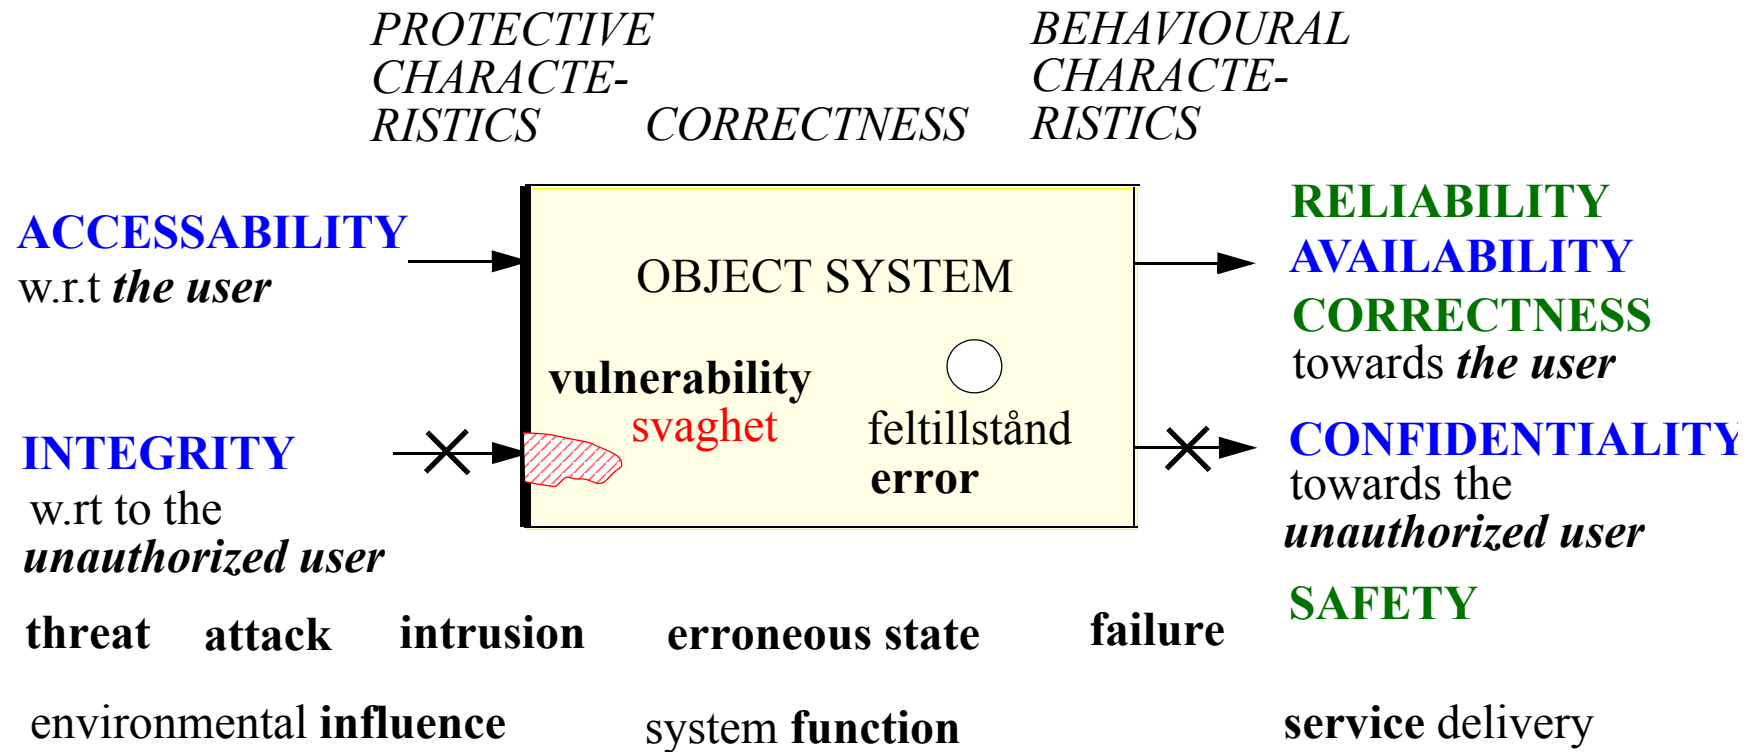

information must be available to the *authorized* user

SECURITY ASPECTS vs OBJECT SYSTEM

DEPENDABILITY ATTRIBUTES vs OBJECT SYSTEM

A FUNDAMENTAL SYSTEM MODEL FOR DEPENDABILITY/SECURITY

<-----INTRUSION DETECTION----->

**THREAT
REDUCTION**

**BOUNDARY
PROTECTION**

RECOVERY

*PROTECTIVE
CHARACTE-
RISTICS*

CORRECTNESS

*BEHAVIOURAL
CHARACTE-
RISTICS*

ACCESSABILITY

w.r.t *the user*

OBJECT SYSTEM

**RELIABILITY
AVAILABILITY**

CORRECTNESS
towards *the user*

INTEGRITY

w.rt to the
unauthorized user

vulnerability

svaghet

○
feltillstånd
error

CONFIDENTIALITY
towards the
unauthorized user

threat

attack

intrusion

erroneous state

failure

SAFETY

environmental **influence**

system **function**

service delivery

EXAMPLES of PROTECTION MECHANISMS - IN PRINCIPLE

- *preventive protection - threat reduction:*
 - legal protection
 - reducing threats (e.g. “security check-ups”)
 - **education / information / propaganda!**
- *boundary protection:*
 - shield cables
 - encryption
 - physical protection (e.g. locks)
 - access control
- *internal protection - recovery:*
 - (anti-)virusprograms
 - supervision mechanisms (with recovery capabilities)
 - encryption of stored data

A BIOLOGICAL ANALOGY

AN ANALOGY TO HUMAN BEINGS

**THREAT
REDUCTION**

**BOUNDARY
PROTECTION**

RECOVERY

PROTECTION

HEALTH
system **function**

BEHAVIOUR

environmental
influence

HUMAN BEING

vulnerability
svaghet

**service
delivery**

germs

wound

fever

being ill/death

threat

attack

intrusion

erroneous state

failure

SOME OBSERVATIONS FROM THE BIOLOGICAL ANALOGY

- **THREATS:**

Threats are there all the time.

Threats change and evolve.

- **PROTECTION MECHANISMS:**

Protection takes place at different levels.

Protection mechanisms are active continuously.

Protection mechanisms must also change and evolve according to the threats.

Even anticipatory protection exists. (inoculation)

- + **Hypothesis:**

Modern IT systems are so complicated so that **a biological paradigm must be adapted**. Thus, security protection must be a **continuous process**, taking place simultaneously on **all protection levels**. Security protection must be **adaptive**.

THE TIME ASPECT

THE TIME ASPECT - SOME OBSERVATIONS

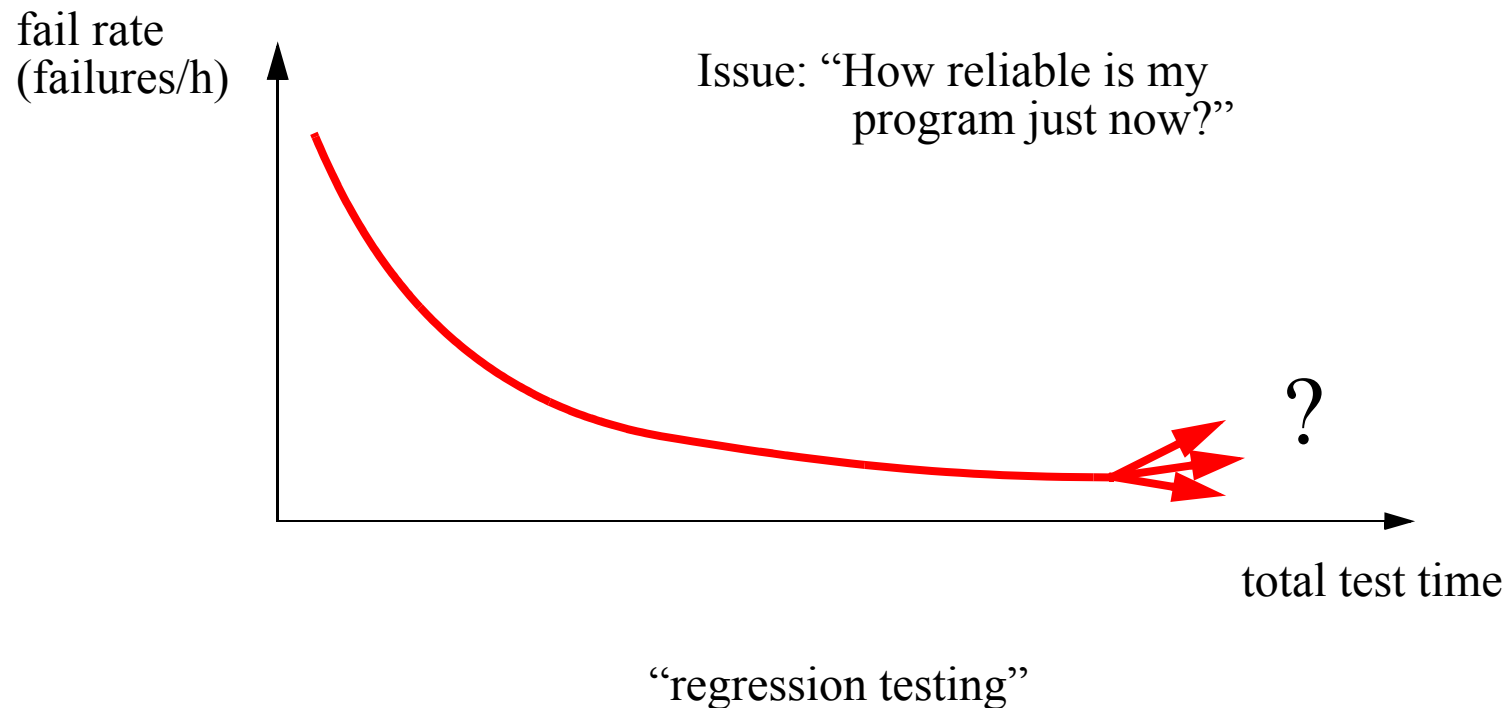

- The **time aspect is very often neglected** in security analysis. It must be noted that:
 - introduction of a fault into the system does not mean that the system fails immediately. It may never fail due to this fault. The **latency** aspect - **fault propagation**.
 - the **latency** clearly **affects metrics** of system behaviour. There might be a substantial time between the original fault occurrence and the resulting (deficient) system behaviour.
 - faults can be introduced into a system **throughout its lifetime**. Many faults are introduced during the design phase.
 - Some security mechanisms do not protect the system as it stands. But it will give information for improving subsequent generations. (E.g. intrusion detection)

THE TIME ASPECT - DEBUGGING (A software analogy)

“the law of diminishing results”

(regarding debugging of software):

It will be increasingly hard to find the remaining faults

THE TIME ASPECT - LATENCY (Another software analogy)

- A program can have many errors with very long MTTF.
- An investigation of an IBM-program showed that more than 30% of the errors had an **MTTF > 5000 years!!**
This means that if we test the system continuously, after 5000 years some 30 % of the errors remain latent!
(Ref: E. N. Adams: “Optimizing preventive service of software products”, *IBM Journal of Research and Development*, vol. 28, No. 1, pp. 2-14, 1984.)
- The same problem applies to *security vulnerabilities*

SUMMING UP

A FEW OBSERVATIONS

- Make a distinction between **non-functional** and **functional** attributes
- The desirable behaviour of a system depends on the **intended user**
- System **latency** affects system behaviour (e.g. reliability, availability, etc)
- Introduction of faults, errors and vulnerabilities can be throughout **the system's lifecycle**
- a **security** problem is **not the same as** a **reliability** problem but they are related (in a complicated way)

CONCLUSIONS (general)

- The areas of Dependability and Security have traditionally evolved separately and there is still a lack of coordination between them regarding concepts, terms, tools etc
- Dependability and Security reflect two different approaches to the same fundamental research area
- Dependability and Security must be **integrated into one common context** in order for us to be able to properly address the problems involved

CONCLUSIONS (specific)

- We have suggested an *integrated system model* for Dependability and Security, describing the system in terms of *correctness* as well as *protective* and *behavioural characteristics*
- Dependability and Security metrics could be defined in accordance
- Protection methods and mechanisms have been related to the system model
- Intrusion detection is a mechanisms that introduces the “product-in-a-process” concept for the system

EXTENSIONS/COMPLICATIONS

Why is this just part of the truth?

There are a number of issues that are not addressed and extensions to be made to make things more realistic:

- add feedback
- non-binary output (degraded performance)
- non-binary input (“gradual attack”)
- multiple causes for an attack

- cascading of systems
- hierarchical systems (“systems-of-systems”)
