

# Database Construction and Usage

SQL DDL and DML  
Relational Algebra

# Announcement

- Attributes on ER relationships are allowed
  - But boolean “flag” attributes are discouraged
- Sign up to the Google Group for updates!
  - <https://groups.google.com/forum/#!forum/tda357-ht2016>
- Fill in the doodles
  - No-one signed up == no TA attending
  - More rooms are added if needed

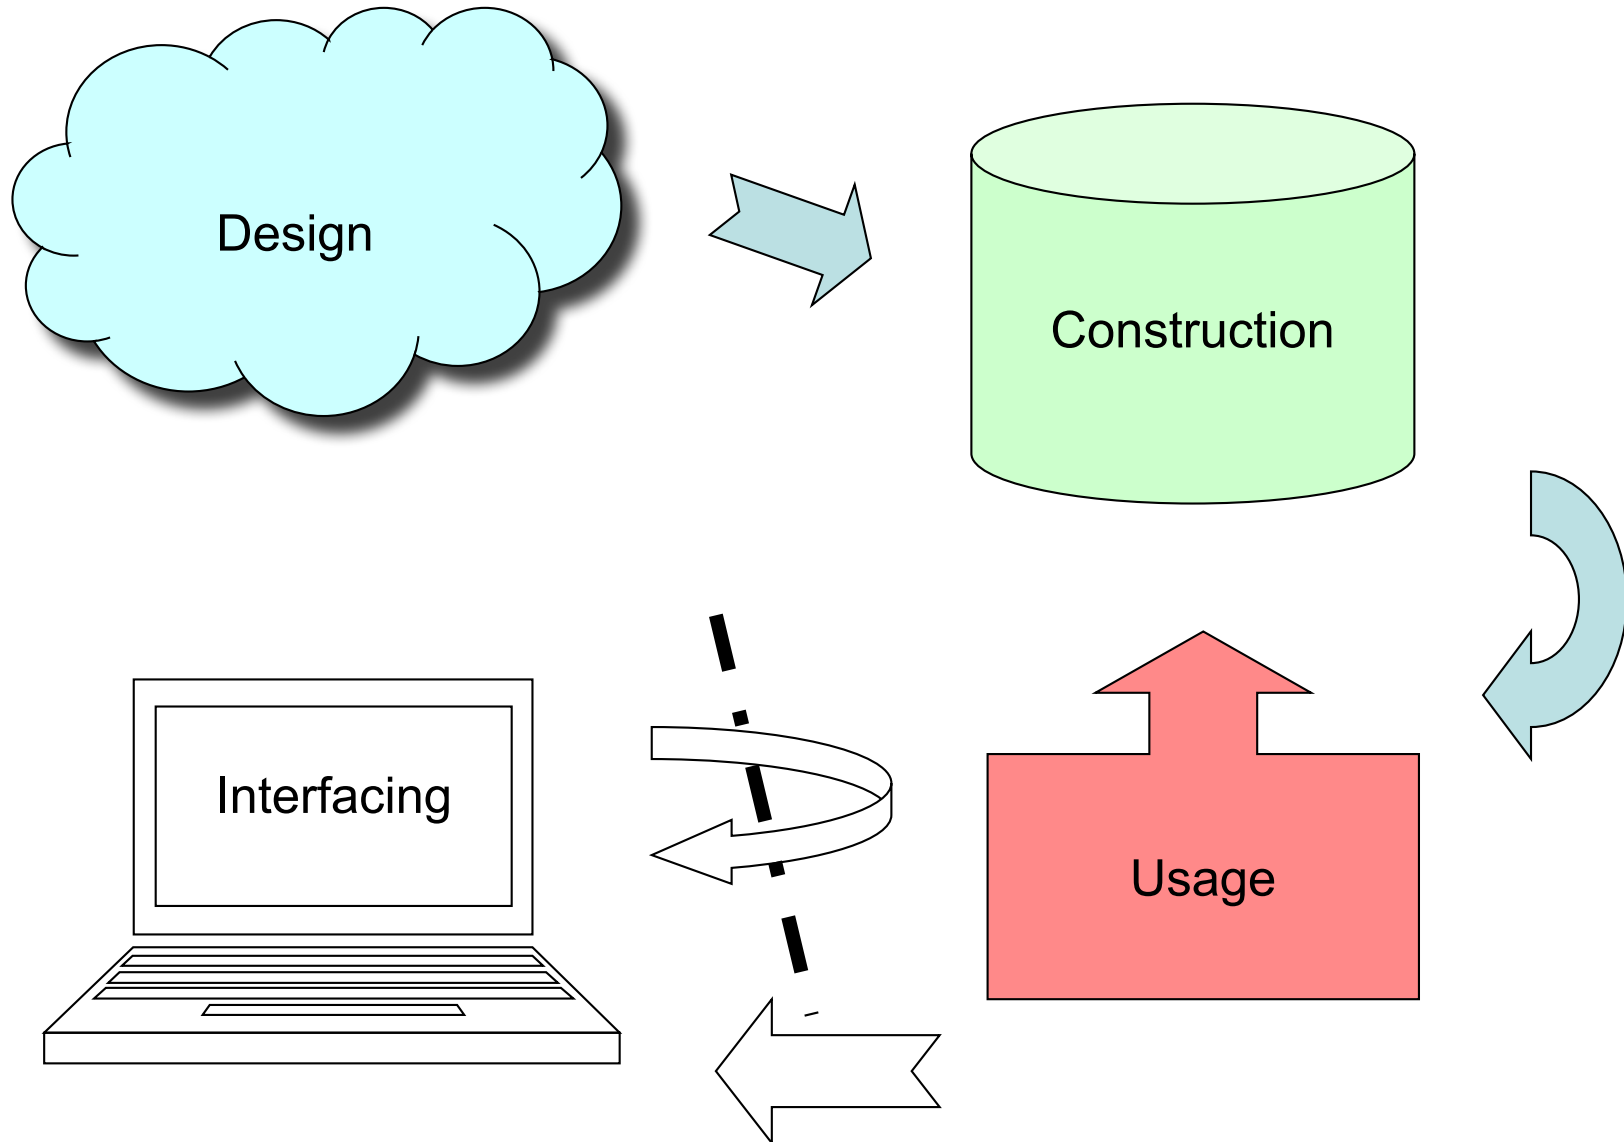

# Example

	Room A	Room B
Alice	✓	
Bob	✓	
Charlie	✓	
	3	0

Alice, Bob and Charlie signed up for room A  
No-one signed up for room B

**In this case, there will be NO  
teaching assistant in room B!!**

# Course Objectives

# Connecting to PostgreSQL

- Chalmers postgresql server (check Fire for your credentials):

```
psql -h ate.ita.chalmers.se -U <username> <dbname>
```

- Local postgresql server:

```
psql <dbname>
```

- Semicolon and postgres prompt:

```
steven=> select 1+1 
```

```
steven-> ;
```

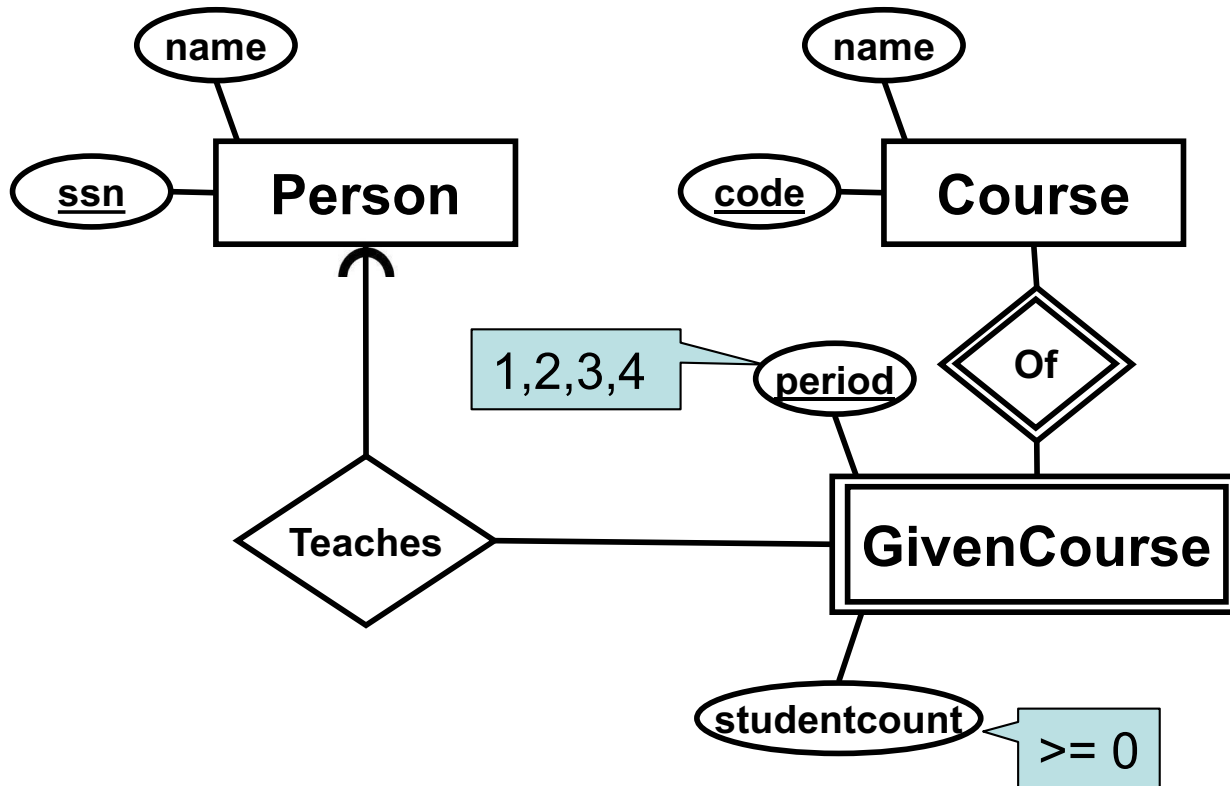

Lines should end with ';', otherwise statements are continued on the next line. Note the prompt change!

# Case convention

- SQL is completely case insensitive. Upper-case or Lower-case makes no difference. We will use case in the following way:
  - **UPPERCASE** marks keywords of the SQL language.
  - **lowercase** marks the name of an attribute.
  - **Capitalized** marks the name of a table.

# SQL Data Definition Language

# Working example

Person (ssn, name)

Course (code, name)

GivenCourse (code, period, studentcount, teacher)

code -> Course.code

teacher -> Person.ssn

# Creating and dropping tables

- Relations become tables, attributes become columns.

```
CREATE TABLE Tablename (  
    <list of table elements>  
);
```

- Get all info about a created table:

```
\d+ Tablename;
```

PostgreSQL specific!

- Remove a created table:

```
DROP TABLE Tablename;
```

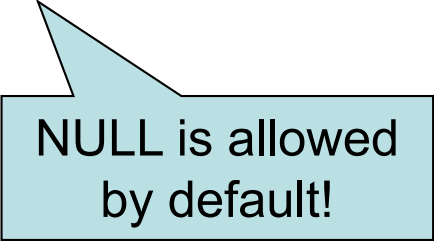

# Table declaration elements

- The basic elements are pairs consisting of a column name and a type.
- Most common SQL types:
  - INT or INTEGER (synonyms)
  - REAL or FLOAT (synonyms)
  - CHAR( $n$ ) = fixed-size string of size  $n$ .
  - VARCHAR( $n$ ) = variable-size string of up to size  $n$ .
  - TEXT = string of unrestricted length

# Example

Example:

```
CREATE TABLE Courses (  
    code CHAR(6),  
    name TEXT NOT NULL  
);
```

NULL is allowed  
by default!

Created the table courses:

code	name
------	------

# Declaring keys

- An attribute or a list of attributes can be declared PRIMARY KEY or UNIQUE
  - PRIMARY KEY: (At most) One per table, never NULL. Efficient lookups in all DBMS.
  - UNIQUE: Any number per table, can be NULL. Could give efficient lookups (may vary in different DBMS).
- Both declarations state that all other attributes of the table are functionally determined by the given attribute(s).

# Example

```
CREATE TABLE Courses(  
  code CHAR(6),  
  name TEXT NOT NULL,  
  PRIMARY KEY (code)  
);
```

# Foreign keys

- Referential constraints are handled with references, called *foreign keys*.
  - FOREIGN KEY *attribute*  
REFERENCES *table(attribute)*.

**FOREIGN KEY course**

**REFERENCES Courses (code)**

# Foreign keys

- General:

```
FOREIGN KEY course REFERENCES Courses (code)
```

- If course is Primary Key in Courses:

```
FOREIGN KEY course  
REFERENCES Courses
```

- Give a name to the foreign key:

```
CONSTRAINT ExistsCourse  
FOREIGN KEY course  
REFERENCES Courses
```

# Example

```
CREATE TABLE GivenCourses (  
  course          CHAR(6),  
  period          INT,  
  numStudents    INT,  
  teacher         INT REFERENCES People(ssn) NOT  
  NULL,  
  PRIMARY KEY (course, period),  
  FOREIGN KEY (course) REFERENCES Courses(code)  
);
```

# Example

```
CREATE TABLE GivenCourses (  
    course CHAR(6) REFERENCES Courses,  
    period          INT,  
    numStudents    INT,  
    teacher        INT REFERENCES People(ssn) NOT  
    NULL,  
    PRIMARY KEY (course, period)  
);
```

# Value constraints

- Use CHECK to insert simple value constraints.
  - CHECK (*some test on attributes*)

**CHECK (period IN (1,2,3,4) )**

# Example

```
CREATE TABLE GivenCourses (  
  course CHAR(6) REFERENCES Courses,  
  period          INT CHECK (period IN (1,2,3,4)),  
  numStudents    INT,  
  teacher        INT REFERENCES People(ssn) NOT  
  NULL,  
  PRIMARY KEY (course, period)  
);
```

# Example

```
CREATE TABLE GivenCourses (  
  course CHAR(6) REFERENCES Courses,  
  period          INT,  
  numStudents    INT,  
  teacher        INT REFERENCES People(ssn) NOT  
  NULL,  
  PRIMARY KEY (course, period),  
  CONSTRAINT ValidPeriod CHECK (period in (1,2,3,4))  
);
```

# SQL Data Manipulation Language: Modifications

# Inserting data

```
INSERT INTO tablename  
VALUES (values for attributes);
```

```
INSERT INTO Courses  
VALUES ('TDA357', 'Databases');
```

<i>code</i>	<i>name</i>
TDA357	Databases

# Example

- **Legal:**

- INSERT INTO GivenCourses  
VALUES ('TDA357', 2, 199, 1);

- **Not Legal:**

- INSERT INTO GivenCourses  
VALUES ('TDA357', 7, 199, 1);

- **ERROR:** new row for relation  
"givencourses" violates check constraint  
"givencourses\_period\_check"DETAIL:  
Failing row contains (TDA357, 7, 199, 1).

# Deletions

```
DELETE FROM tablename  
WHERE test over rows;
```

```
DELETE FROM Courses  
WHERE code = 'TDA357' ;
```

# Updates

```
UPDATE tablename  
SET attribute = ...  
WHERE test over rows
```

```
UPDATE GivenCourses  
SET teacher = 'Graham Kemp'  
WHERE course = 'TDA357'  
AND period = 2;
```

# Queries: SQL and Relational Algebra

# Querying

- To *query* the database means asking it for information.
  - "List all courses that have lectures in room VR"
- Unlike a modification, a query leaves the database unchanged.

# SQL

- SQL = Structured Query Language
  - The querying parts are really the core of SQL. The DDL and DML parts are secondary.
- Very-high-level language.
  - Specify *what* information you want, not *how* to get that information (like you would in e.g. Java).
- Based on Relational Algebra

# ”Algebra”

- An *algebra* is a mathematical system consisting of:
  - Operands: variables or values to operate on.
  - Operators: symbols denoting functions that operate on variables and values.

# Relational Algebra

- An algebra whose operands are relations (or variables representing relations).
- Operators representing the most common operations on relations.
  - Selecting rows
  - Projecting columns
  - Composing (joining) relations

# Selection

- Selection = Given a relation (table), choose what tuples (rows) to include in the result.

$$\boxed{\sigma_C(T)} \quad \text{SELECT * FROM T WHERE C;}$$

- Select the rows from relation T that satisfy condition C.
- $\sigma$  = sigma = greek letter **S** = **S**election

Example:

GivenCourses =

<i>course</i>	<i>per</i>	<i>teacher</i>
TDA357	3	Niklas Broberg
TDA357	2	Graham Kemp
TIN090	1	Devdatt Dubhashi

```
SELECT *  
FROM GivenCourses  
WHERE course = 'TDA357' ;
```

Result =

What?

Example:

GivenCourses =

<i>course</i>	<i>per</i>	<i>teacher</i>
TDA357	3	Niklas Broberg
TDA357	2	Graham Kemp
TIN090	1	Devdatt Dubhashi

```
SELECT *  
FROM GivenCourses  
WHERE course = 'TDA357' ;
```

Result =

<i>course</i>	<i>per</i>	<i>teacher</i>
TDA357	3	Niklas Broberg
TDA357	2	Graham Kemp

# Projection

- Given a relation (table), choose what attributes (columns) to include in the result.

$\pi_X(\sigma_C(T))$     **SELECT X FROM T WHERE C;**

- Select the rows from table T that satisfy condition C, and project columns X of the result.
- $\pi$  = pi = greek letter    **p** = **p**rojection

Example:

GivenCourses =

<i>course</i>	<i>per</i>	<i>teacher</i>
TDA357	3	Niklas Broberg
TDA357	2	Graham Kemp
TIN090	1	Devdatt Dubhashi

```
SELECT course, teacher  
FROM GivenCourses  
WHERE course = 'TDA357';
```

Result =

What?

Example:

GivenCourses =

<i>course</i>	<i>per</i>	<i>teacher</i>
TDA357	3	Niklas Broberg
TDA357	2	Graham Kemp
TIN090	1	Devdatt Dubhashi

```
SELECT course, teacher  
FROM GivenCourses  
WHERE course = 'TDA357' ;
```

Result =

<i>course</i>	<i>teacher</i>
TDA357	Niklas Broberg
TDA357	Graham Kemp

# The confusing **SELECT**

Example:

<u>course</u>	<u>per</u>	<i>teacher</i>
TDA357	3	Niklas Broberg
TDA357	2	Graham Kemp
TIN090	1	Devdatt Dubhashi

GivenCourses =

```
SELECT course, teacher  
FROM GivenCourses;
```

Result =

What?

# The confusing **SELECT**

Example:

GivenCourses =

<i>course</i>	<i>per</i>	<i>teacher</i>
TDA357	3	Niklas Broberg
TDA357	2	Graham Kemp
TIN090	1	Devdatt Dubhashi

**SELECT** *course, teacher*  
**FROM** GivenCourses ;

Result =

<i>course</i>	<i>teacher</i>
TDA357	Niklas Broberg
TDA357	Graham Kemp
TIN090	Devdatt Dubhashi

Quiz: **SELECT** is a projection??

# Mystery revealed!

```
SELECT course, teacher  
FROM GivenCourses;
```

$$\begin{aligned} & \pi_{\text{code,teacher}}(\sigma(\text{GivenCourses})) \\ &= \pi_{\text{code,teacher}}(\text{GivenCourses}) \end{aligned}$$

- In general, the SELECT clause could be seen as corresponding to projection, and the WHERE clause to selection (don't confuse the naming though).

# Quiz!

- What does the following expression compute?

Courses

<u>code</u>	<i>name</i>
TDA357	Databases
TIN090	Algorithms

GivenCourses

<u>course</u>	<u>per</u>	<i>teacher</i>
TDA357	3	Niklas Broberg
TDA357	2	Graham Kemp
TIN090	1	Devdatt Dubhashi

```
SELECT *  
FROM Courses, GivenCourses  
WHERE teacher = 'Niklas Broberg' ;
```

# FROM Courses, GivenCourses

<i>code</i>	<i>name</i>	<i>course</i>	<i>per</i>	<i>teacher</i>
TDA357	Databases	TDA357	3	Niklas Broberg
TDA357	Databases	TDA357	2	Graham Kemp
TDA357	Databases	TIN090	1	Devdatt Dubhashi
TIN090	Algorithms	TDA357	3	Niklas Broberg
TIN090	Algorithms	TDA357	2	Graham Kemp
TIN090	Algorithms	TIN090	1	Devdatt Dubhashi

**WHERE teacher = 'Niklas  
Broberg'**

<i>code</i>	<i>name</i>	<i>course</i>	<i>per</i>	<i>teacher</i>
<b>TDA357</b>	<b>Databases</b>	<b>TDA357</b>	<b>3</b>	<b>Niklas Broberg</b>
TDA357	Databases	TDA357	2	Graham Kemp
TDA357	Databases	TIN090	1	Devdatt Dubhashi
<b>TIN090</b>	<b>Algorithms</b>	<b>TDA357</b>	<b>3</b>	<b>Niklas Broberg</b>
TIN090	Algorithms	TDA357	2	Graham Kemp
TIN090	Algorithms	TIN090	1	Devdatt Dubhashi

Answer:

```
SELECT *  
FROM Courses, GivenCourses  
WHERE teacher = 'Niklas Broberg' ;
```

<i>code</i>	<i>name</i>	<i>course</i>	<i>per</i>	<i>teacher</i>
TDA357	Databases	TDA357	3	Niklas Broberg
TIN090	Algorithms	TDA357	3	Niklas Broberg

The result is all rows from **Courses** combined in all possible ways with all rows from **GivenCourses**, and then keep only those where the **teacher** attribute is Niklas Broberg.

# Cartesian Products

- The *cartesian product* of relations  $R_1$  and  $R_2$  is all possible combinations of rows from  $R_1$  and  $R_2$ .
  - Written  $R_1 \times R_2$
  - Also called *cross-product*, or just *product*

```
SELECT *  
FROM   Courses, GivenCourses  
WHERE  teacher = 'Niklas Broberg';
```

$\sigma_{\text{teacher} = \text{'Niklas Broberg'}}(\text{Courses} \times \text{GivenCourses})$

# Quiz!

List all courses, with names, that Niklas Broberg is responsible for.

**Courses** (*code*, *name*)

**GivenCourses** (*course*, *per*, *teacher*)

*course* -> **Courses**.*code*

**SELECT** \*

**FROM** **Courses**, **GivenCourses**

**WHERE** *teacher* = 'Niklas Broberg'

**AND** *code* = *course*;

<i>code</i>	<i>name</i>	<i>course</i>	<i>per</i>	<i>teacher</i>
TDA357	Databases	TDA357	3	Niklas Broberg

**code = course**

<i>code</i>	<i>name</i>	<i>course</i>	<i>per</i>	<i>teacher</i>
<b>TDA357</b>	<b>Databases</b>	<b>TDA357</b>	<b>3</b>	<b>Niklas Broberg</b>
TDA357	Databases	TDA357	2	Graham Kemp
TDA357	Databases	TIN090	1	Devdatt Dubhashi
<b>TIN090</b>	<b>Algorithms</b>	<b>TDA357</b>	<b>3</b>	<b>Niklas Broberg</b>
TIN090	Algorithms	TDA357	2	Graham Kemp
TIN090	Algorithms	TIN090	1	Devdatt Dubhashi

Not equal

# Joining relations

- Very often we want to join two relations on the value of some attributes.
  - Typically we join according to some reference, as in:

```
SELECT *  
FROM Courses, GivenCourses  
WHERE code = course;
```

- Special operator  $\bowtie_C$  for joining relations.

$$R_1 \bowtie_C R_2 = \sigma_C(R_1 \times R_2)$$

```
SELECT *  
FROM R1 JOIN R2 ON C;
```

# Example

Courses

<i>code</i>	<i>name</i>
TDA357	Databases
TIN090	Algorithms

GivenCourses

<i>course</i>	<i>per</i>	<i>teacher</i>
TDA357	3	Niklas Broberg
TDA357	2	Graham Kemp
TIN090	1	Devdatt Dubhashi

```
SELECT *  
FROM Courses JOIN GivenCourses  
ON code = course;
```

<i>code</i>	<i>name</i>	<i>course</i>	<i>per</i>	<i>teacher</i>
TDA357	Databases	TDA357	3	Niklas Broberg
TDA357	Databases	TDA357	2	Graham Kemp
TIN090	Algorithms	TIN090	1	Devdatt Dubhashi

# Natural join

- "Magic" version of join.
  - Join two relations on the condition that all attributes in the two that share the same name should be equal.
  - Remove all duplicate columns
  - Written  $R_1 \bowtie R_2$  (like join with no condition)

# Example

Courses

<u>code</u>	<i>name</i>
TDA357	Databases
TIN090	Algorithms

GivenCourses

<u>code</u>	<u>per</u>	<i>teacher</i>
TDA357	3	Niklas Broberg
TDA357	2	Graham Kemp
TIN090	1	Devdatt Dubhashi

```
SELECT *  
FROM Courses NATURAL JOIN GivenCourses;
```

<i>code</i>	<i>name</i>	<i>per</i>	<i>teacher</i>
TDA357	Databases	3	Niklas Broberg
TDA357	Databases	2	Graham Kemp
TIN090	Algorithms	1	Devdatt Dubhashi

# Sets or Bags?

- Relational algebra formally applies to sets of tuples.
- SQL, the most important query language for relational databases is actually a bag language.
  - SQL will eliminate duplicates, but usually only if you ask it to do so explicitly.
- Some operations, like projection, are much more efficient on bags than sets.

# Sets or Bags?

R(A,B)

A	B
1	2
5	6
1	3

**SQL**

```
SELECT A  
FROM R
```

A
1
5
1

Bag

**Relational  
Algebra**

$\pi_A(R)$

A
1
5

Set

(no repeating values)
