Answering questions at approx 15.00 (or by phone)

Functional Programming TDA 452, DIT 142

2017-01-12 14.00 - 18.00 "Maskin"-salar (M)

- There are 6 questions with maximum 6+9+7+6+6+6=40 points; a total of 20 points definitely guarantees a pass.
- Results: latest approximately 10 days.
- Permitted materials:
 - Dictionary
- Please read the following guidelines carefully:
 - Read through all Questions before you start working on the answers.
 - Begin each Question on a new sheet.
 - Write clearly; unreadable = wrong!
 - For each part Question, if your solution consists of more than a few lines of Haskell code, use your common sense to decide whether to include a short comment to explain your solution.
 - You can use any of the standard Haskell functions listed at the back of this exam document.
 - Full points are given to solutions which are short, elegant, and correct. Fewer
 points may be given to solutions which are unnecessarily complicated or unstructured.
 - You are encouraged to use the solution to an earlier part of a Question to help solve a later part even if you did not succeed in solving the earlier part.

1. (6 points)

(a) (3 points) Give a define of the function

```
findIndices :: (a->Bool) -> [a] -> [Int]
```

that given a test and a list returns the *indexes* of the elements in the list that pass the test. Examples:

```
findIndices isUpper "Hello World" == [0,6]
findIndices isDigit "Hello World" == []
filter isUpper "Hello World" == "HW"
```

```
Solution:
findIndices p xs = [i|(i,x)<-zip [0..] xs,p x]</pre>
```

(b) (3 points) Write a property to verify that the elements at the indexes returned by findIndices pass the test.

findIndices_v2 p = map fst . filter (p.snd) . zip [0..]

```
prop_findIndices :: (a->Bool) -> [a] -> Bool
```

```
Solution:
    prop_findIndices p xs = and [p (xs!!i) | i<-is]
    where is = findIndices p xs

-- Also accepted, although it doesn't test exactly what was asked for...
    prop_findIndices_v2 p xs = [xs!!i | i<-findIndices p xs] == filter p xs</pre>
```

2. (9 points)

(a) (3 points) The following function works as intended, but the code is not as simple and efficient as it could be:

Simplify the code as much as you can. In particular, use pattern matching instead of fst, snd, length, head, tail and drop.

```
Solution:
    split' :: [a] -> ([a],[a])
    split' (x1:x2:xs) = (x1:xs1,x2:xs2) where (xs1,xs2) = split' xs
    split' xs = (xs,[])
```

(b) (3 points) Define a function merge that merges two sorted lists into a sorted list.

```
merge :: Ord a => [a] -> [a] -> [a]
```

(c) (3 points) Define a function mergeSort that sorts a list by splitting it into two parts, recursively sorting the parts, and merging the results.

```
mergeSort :: Ord a => [a] -> [a]
```

```
Solution:
  mergeSort [] = []
  mergeSort [x] = [x]
  mergeSort xs = merge (mergeSort xs1) (mergeSort xs2)
  where (xs1,xs2) = split xs
```

3. (7 points)

(a) (2 points) Define a data type Tree a for binary trees that have empty leaves and a value of type a in each internal node.

```
Solution:

data Tree a = Empty | Branch a (Tree a) (Tree a)

deriving (Eq,Show) -- optional
```

(b) (3 points) Define an instance Functor Tree with the expected behaviour for the standard class Functor, defined as

```
class Functor f where fmap :: (a->b) \rightarrow f a \rightarrow f b
```

```
Solution:
  instance Functor Tree where
  fmap f Empty = Empty
  fmap f (Branch x l r) = Branch (f x) (fmap f l) (fmap f r)
```

(c) (2 points) Define a function doubleTree that doubles all the numbers in a tree of numbers.

```
doubleTree :: Num a => Tree a -> Tree a
```

```
Solution:
doubleTree = fmap (*2)
```

4. (6 points) For each of the following functions, give the most general type, or write No type if the definition is not type correct in Haskell.

```
a x = (x,x)

b x y = x < y+1

c x (y,z) = x y z
```

Solution:

```
a :: x -> (x,x)
b :: (Ord a,Num a) => a -> a -> Bool
c :: (y->z->x)->(y,z)->x -- c = uncurry
```

- 5. (6 points)
 - (a) (2 points) Given a function

```
parse :: Parser a -> String -> Maybe (a,String)
```

that applies a parser to an input string and returns Nothing if the parser fails, and Just (a,s) if the parser succeeds, where a is the result of the parser and s is the remaining unused input. Define

```
completeParse :: Parser a -> String -> Maybe a
```

that succeeds and returns Just a only if the parser accepted all of the input string (i.e., the remaining input is empty). (*Hint:* you don't need to know anything more about the Parser type in order to answer this question.)

- (b) (4 points) The QuickCheck function vectorOf generates a list of a given length, using a given generator for the elements. Implement two versions of vectorOf:
 - i. Using only standard library functions.
 - ii. Using recursion directly.

```
vectorOf_i, vectorOf_ii :: Int -> Gen a -> Gen [a]
```

- 6. (6 points) The Luhn algorithm is used to check bank card numbers for simple errors such as mistyping a digit, and proceeds as follows:
 - consider each digit as a separate number;
 - moving left, double every other number from the second last;
 - subtract 9 from each number that is now greater than 9;
 - add all the resulting numbers together;
 - if the total is divisible by 10, the card number is valid

Define a function validCard and suitable helper functions to check if a bank card number is valid according to the above algorithm.

```
Solution:
-- Compact version
validCard = (==0) . ('mod' 10) . sum .
             map sub9 . zipWith (*) (cycle [1,2]) .
             reverse . map digitToInt . show
     sub9 n = if n>9 then n-9 else n
-- More verbose, self-documenting variant
validCard_v2 :: Integer -> Bool
 validCard_v2 n = luhn n 'mod' 10 == 0
   where
     luhn = sum . map subtract9 . doubleEveryOther . integerToList
     subtract9 n = if n>9 then n-9 else n
     integerToList :: Integer -> [Int]
     integerToList = reverse . map (\x->read [x]) . show
     doubleEveryOther :: [Int] -> [Int]
    doubleEveryOther []
                                 = []
     doubleEveryOther [d]
                                 = [d]
     doubleEveryOther (d1:d2:ds) = d1:(2*d2):doubleEveryOther ds
```

```
even n
odd
            liftM
liftM
                                                                                                                                                                                                                                                               even, odd
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        class (Eq a, Show a) => Num a where (+), (-), (*) :: a -> a -> a
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  This is a list of selected functions from the standard Haskell modules: Prelude Data.List
                                                                     sequence_ xs
                                                                                                                                                             sequence
                                                                                                                                                                           sequence
                                                                                                                                                                                                                                                                                                                                                                        class (Real a, Fractional a) => RealFrac a where
                                                                                                                                                                                                                                                                                                                                                                                                                                  class (Fractional a) => Floating a where
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            class (Num a) =>
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     class (Real a,
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  class (Num a, Ord a) => Real a where
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  class (Eq a) => Ord a where
