Learning to act in an unknown environment, by interaction and reinforcement.

590

イロト イヨト イヨト イヨト

Learning to act in an unknown environment, by interaction and reinforcement.

Markov decision processes (MDP)

We are in some environment μ , where at each time step *t*:

- Observe state $s_t \in S$.
- **Take action** $a_t \in \mathcal{A}$.
- Receive reward $r_t \in \mathbb{R}$.

イロト イヨト イヨト イヨト

SAC

Learning to act in an unknown environment, by interaction and reinforcement.

The optimal policy for a given w

• Find policy $\pi : S \to A$ maximising the utility $U = \sum_t r_t$ in expectation.

 r_{t+1}

 (S_{t+})

イロト イポト イヨト イヨト

Learning to act in an unknown environment, by interaction and reinforcement.

μ (r_{t+1}) (r_{t+1}) (s_t) (s_{t+1}) (s_t)

イロト イポト イヨト イヨト

The optimal policy for a given w

- Find policy $\pi : S \to A$ maximising the utility $U = \sum_t r_t$ in expectation.
- When *w* is known, use standard algorithms, such as value or policy iteration. However this is

Learning to act in an unknown environment, by interaction and reinforcement.

• Receive reward $r_t \in \mathbb{R}$.

イロト イポト イヨト イヨト

The optimal policy for a given w

- Find policy $\pi: S \to A$ maximising the utility $U = \sum_t r_t$ in expectation.
- When *w* is known, use standard algorithms, such as value or policy iteration. However this is contrary to the problem definition!

Learning to act in an unknown environment, by interaction and reinforcement.

Markov decision processes (MDP) We are in some environment μ , where at each time step t: • Observe state $s_t \in S$.

- Take action $a_t \in \mathcal{A}$.
- Receive reward $r_t \in \mathbb{R}$.

Bayesian RL: Use a subjective belief $\xi(\mu)$

$$\mathbb{E}(U \mid \pi, \xi)$$

-

Sar

Learning to act in an unknown environment, by interaction and reinforcement.

- Receive reward $r_t \in \mathbb{R}$.

< ロト < 回 ト < 回 ト < 三</p>

Bayesian RL: Use a subjective belief $\xi(\mu)$

$$\mathbb{E}(U \mid \pi, \xi) = \sum_{\mu} \mathbb{E}(U \mid \pi, \mu) \xi(\mu)$$

Sar

Learning to act in an unknown environment, by interaction and reinforcement.

- Take action $a_t \in A$.
- Receive reward $r_t \in \mathbb{R}$.

・ロト ・回 ・ ・ ヨト ・

Bayesian RL: Use a subjective belief $\xi(\mu)$

Not actually easy as π must now map from complete histories to actions.

$$U^*_{\xi} = \max_{\pi} \mathbb{E}(U \mid \pi, \xi) = \max_{\pi} \sum_{\mu} \mathbb{E}(U \mid \pi, \mu) \xi(\mu)$$

Planning must take into account future learning

Christos Dimitrakakis (EPFL)

nar

Updating the belief

Example

When the number of MDPs is finite

Exercise

Another practical scenario is when we have an independent belief over the transition probabilities of each state-action pair. Consider the case where we have n states and k actions. Similar to the product-prior in the bandit exercise of exercise set 4, we assign a probability (density) $\xi_{s,a}$ to the probability vector $\theta_{(s,a)} \in \mathbb{S}^n$. We can then define our joint belief on the $(nk) \times n$ matrix Θ to be

$$\xi(\boldsymbol{\varTheta}) = \prod_{s \in \mathcal{S}, s \in \mathcal{A}} \xi_{s,s}(\boldsymbol{\theta}_{(s,s)}).$$

Derive the updates for a product-Dirichlet prior on transitions and a product-Normal-Gamma prior on rewards. What is the meaning of using a Normal-Wishart prior on rewards?

イロト イポト イヨト イヨト

The expected MDP heuristic

I For a given belief ξ , calculate the expected MDP:

$$\bar{\mu}_{\xi} \triangleq \mathbb{E}_{\xi} \, \mu.$$

2 Calculate the optimal memoryless policy for $\bar{\mu}_{\mathcal{E}}$:

$$\pi^*(ar\mu_\xi)\in rgmax_{\pi\in\Pi_1}V^\pi_{ar\mu_\xi},$$

where
$$\Pi_1 = \{ \pi \in \Pi \mid \mathbb{P}_{\pi}(a_t \mid s^t, a^{t-1}) = \mathbb{P}_{\pi}(a_t \mid s_t) \}.$$

B Execute $\pi^*(\mu_{\xi})$.

Problem

Unfortunately, this approach may be far from the optimal policy in Π_1 .

nac

<ロ> (日) (日) (日) (日) (日)

Counterexample¹

Figure: $\mathcal{M} = \{\mu_1, \mu_2\}, \ \xi(\mu_1) = \theta, \ \xi(\mu_2) = 1 - \theta$, deterministic transitions.

• For $T \to \infty$, the $\bar{\mu}_{\xi}$ -optimal policy is not optimal in Π_1 if:

$$\epsilon < \frac{\gamma \theta (1-\theta)}{1-\gamma} \left(\frac{1}{1-\gamma \theta} + \frac{1}{1-\gamma (1-\theta)} \right)$$

- In this example, $\bar{\mu}_{\xi} \notin \mathcal{M}$.
- For smooth beliefs, $\bar{\mu}_{\xi}$ is close to $\hat{\mu}_{\xi}^*$.

¹Based on one by Remi Munos

Christos Dimitrakakis (EPFL)

イロト イポト イヨト イ

Counterexample for $\hat{\mu}_{\xi}^* \triangleq \arg \max_{\mu} \xi(\mu)$

MDP set $\mathcal{M} = \{\mu_i \mid i = 1, ..., n\}$ with $\mathcal{A} = \{0, ..., n\}$. In all MDPs, a_0 gives you a reward of ϵ and the MDP terminates. In the *i*-th MDP, all other actions give you a reward of 0 apart from the *i*-th action which gives you a reward of 1.

Figure: The MDP μ_i .

- The ξ -optimal policy takes action *i* iff $\xi(\mu_i) \ge \epsilon$, otherwise takes action 0.
- The $\hat{\mu}_{\xi}^*$ -optimal policy takes $a = \arg \max_i \xi(\mu_i)$.

イロト イポト イヨト イヨト

Policy evaluation

Expected utility of a policy π for a belief ξ

$$V_{\xi}^{\pi} \triangleq \mathbb{E}(U \mid \xi, \pi) \tag{2.1}$$

$$= \int_{\mathcal{M}} \mathbb{E}(U \mid \mu, \pi) \,\mathrm{d}\xi(\mu) \tag{2.2}$$

$$= \int_{\mathcal{M}} V^{\pi}_{\mu} \,\mathrm{d}\xi(\mu) \tag{2.3}$$

Bayesian Monte-Carlo policy evaluation

input policy π , belief ξ for k = 1, ..., K do $\mu_k \sim \xi$. $v_k = V_{\mu_k}^{\pi}$ end for $u = \frac{1}{K} \sum_{k=1}^{K} v_k$. return u.

イロン 不聞と 不同と 不同と

Upper bounds on the utility for a belief ξ

$$V_{\xi}^{*} \triangleq \sup_{\pi} \mathbb{E}(U \mid \xi, \pi) = \sup_{\pi} \int_{\mathcal{M}} \mathbb{E}(U \mid \mu, \pi) \,\mathrm{d}\xi(\mu)$$
(2.4)

$$\leq \int_{\mathcal{M}} \sup_{\pi} V_{\mu}^{\pi} \,\mathrm{d}\xi(\mu) = \int_{\mathcal{M}} V_{\mu}^{*} \,\mathrm{d}\xi(\mu) \triangleq V_{\xi}^{+} \tag{2.5}$$

<ロ> (日) (日) (日) (日) (日)

Better lower bounds [?]

Main idea: maximisation in memoryless policies

- Then we can assume a fixed belief.
- Backwards induction on n MDPs
- This improves the naive lower bound.

(4) ⊕ (1) ≥ (1)

Sac

$$Q_{\xi,t}^{\pi}(s,a) \triangleq \int_{\mathcal{M}} \left\{ \bar{R}_{\mu}(s,a) + \gamma \int_{\mathcal{S}} V_{\mu,t+1}^{\pi}(s') \, \mathrm{d}\mathcal{T}_{\mu}^{s,a}(s') \right\} \, \mathrm{d}\xi(\mu) \tag{2.6}$$

Multi-MDP Backwards Induction

1: MMBI $\mathcal{M}, \mathcal{E}, \gamma, T$ 2: Set $V_{\mu,T+1}(s) = 0$ for all $s \in S$. 3: for t = T, T - 1, ..., 0 do 4: for $s \in S$, $a \in A$ do Calculate $Q_{\xi,t}(s,a)$ from (2.6) using $\{V_{\mu,t+1}\}$. 5: end for 6· 7: for $s \in S$ do $a_{\xi,t}^*(s) \in rg\max_{a \in \mathcal{A}} Q_{\xi,t}(s,a).$ 8: for $\mu \in \mathcal{M}$ do 9: $V_{\mu,t}(s) = Q_{\mu,t}(s, a_{\varepsilon}^*(s)).$ 10: end for 11. end for 12: 13: end for

4 Execute π_i until $t = t_{i+1}$.

Relation to other work

- For n = 1, this is equivalent to the Thompson sampling used by Strens [?].
- Unlike BOSS [?] it does not become more optimistic as n increases.
- BEETLE[? ?] is a belief-sampling approach.
- Furmston and Barber [?] use approximate inference to estimate policies.

Generalisations

- Policy search for improving lower bounds.
- Search enlarged class of policies
- Examine all history-based policies.

DQC

イロト イヨト イヨト イヨト

Figure: Belief-augmented MDP

The augmented MDP

The optimal policy for the augmented MDP is the ξ -optimal for the original problem.

$$\mathsf{P}(\mathbf{s}_{t+1} \in S \mid \xi_t, \mathbf{s}_t, \mathbf{a}_t) \triangleq \int_S \mathsf{P}_{\mu}(\mathbf{s}_{t+1} \in S \mid \mathbf{s}_t, \mathbf{a}_t) \, \mathrm{d}\xi_t(\mu) \tag{2.7}$$

$$\xi_{t+1}(\cdot) = \xi_t(\cdot \mid s_{t+1}, s_t, a_t)$$
(2.8)

Belief-augmented MDP tree structure

Branch and bound

Value bounds

Let upper and lower bounds q^+ and q^- such that:

$$q^+(\omega, \mathbf{a}) \ge Q^*(\omega, \mathbf{a}) \ge q^-(\omega, \mathbf{a})$$
 (2.9)

$$v^+(\omega) = \max_{a \in \mathcal{A}} Q^+(\omega, a),$$
 $v^-(\omega) = \max_{a \in \mathcal{A}} Q^-(\omega, a).$ (2.10)

$$q^{+}(\omega, \mathbf{a}) = \sum_{\omega'} p(\omega' \mid \omega, \mathbf{a}) \left[r(\omega, \mathbf{a}, \omega') + V^{+}(\omega') \right]$$
(2.11)

$$\boldsymbol{q}^{-}(\omega, \boldsymbol{a}) = \sum_{\omega'} \boldsymbol{p}(\omega' \mid \omega, \boldsymbol{a}) \left[\boldsymbol{r}(\omega, \boldsymbol{a}, \omega') + \boldsymbol{V}^{-}(\omega') \right]$$
(2.12)

Remark

If $q^-(\omega, a) \ge q^+(\omega, b)$ then b is sub-optimal at ω .

(3.1)

< □ > < 同 > < 三 > <

Belief state in POMDPs when μ is known

If μ defines starting state probabilities, then the belief is not subjective

Belief ξ

For any distribution ξ on S, we define:

$$\xi(s_{t+1} \mid a_t, \mu) \triangleq \int_{\mathcal{S}} P_{\mu}(s_{t+1} \mid s_t a_t) \,\mathrm{d}\xi(s_t) \tag{3.2}$$

Belief update

$$\xi_t(s_{t+1} \mid x_{t+1}, r_{t+1}, a_t, \mu) = \frac{P_\mu(x_{t+1}, r_{t+1} \mid s_{t+1})\xi_t(s_{t+1} \mid a_t, \mu)}{\xi_t(x_{t+1} \mid a_t, \mu)}$$
(3.3)

$$\xi_t(s_{t+1} \mid a_t, \mu) = \int_{\mathcal{S}} P_{\mu}(s_{t+1} \mid s_t, a_t, \mu) \, \mathrm{d}\xi_t(s_t) \tag{3.4}$$

$$\xi_t(x_{t+1} \mid a_t, \mu) = \int_{\mathcal{S}} P_{\mu}(x_{t+1} \mid s_{t+1}) \, \mathrm{d}\xi_t(s_{t+1} \mid a_t, \mu) \tag{3.5}$$

Example

If $\mathcal{S}, \mathcal{A}, \mathcal{X}$ are finite, and then we can define

- $\partial_t(j) = P(x_t \mid s_t = j)$
- $A_t(i,j) = P(s_{t+1} = j | s_t = i, a_t).$
- $\bullet b_t(i) = \xi_t(s_t = i)$

We can then use Bayes theorem:

$$\boldsymbol{b}_{t+1} = \frac{\operatorname{diag}(\boldsymbol{p}_{t+1})\boldsymbol{A}_t\boldsymbol{b}_t}{\boldsymbol{p}_{t+1}^{\top}\boldsymbol{A}_t\boldsymbol{b}_t},$$
