Content of the lectures

4 first lectures: introduction to univalent foundation

Roughly cover the first 4 chapters of the Univalent Foundation Program book

2 last lectures: semantics, groupoid model, presheaf models
The goal is to design a suitable formal system for expressing and checking mathematical proofs on a computer.

These issues have close connections with proof theory and foundation of mathematics.

Traditionally, this interaction has been going in one direction.

I will present a new vision on the foundations of mathematics suggested by the quest of a good formal system for expressing mathematical proofs.

In particular, new insight on one of the most basic notion of mathematics the notion of equality.
Current existing foundations

(1) Set theory: ZFC

→ system MIZAR

(2) Category theory
“It is extremely difficult to accept that mathematics is in need of a completely new foundation . . .”

“There is a good reason it is difficult: the existing foundation of mathematics -ZFC, and its main contender for a new foundation -category theory, have been very successful”

It is overcoming the appeal of category theory as a candidate for a new foundation of mathematics that was for me personally most difficult

V. Voevodsky
Univalent Foundations

Any mathematical object is an “object of” a category
Univalent Foundations

Any mathematical object is an “object of” a category

Any mathematical object is an object of a type
Univalent Foundations

Any mathematical object is an "object of" a category

Any mathematical object is an object of a type

Any type comes with its own notion of equality
Simple type theory

(3) Type theory: mostly unknown among mathematicians
(some exceptions: A. Turing, N.G. de Bruijn, T. Hales, V. Voevodsky)

→ systems HOL, Isabelle, Idris, Coq, Agda

1908 Russell *Mathematical Logic as Based on the Theory of Types*

1940 Church *A Formulation of the Simple Theory of Types*
Simple type theory

Uses $\lambda$-calculus notation

Notation which is at the basis of functional programming (LISP, Scheme, Miranda, O’Caml, Haskell) and denotational semantics

Through the work of P.J. Landin, this calculus is very appropriate to describe many features of programming languages
In set theory, a function is essentially a *functional graph* a “static” notion.

Through λ-calculus, we can represent *functions* as *programs*.

Simple types: a type \( o \) which represents the type of “propositions”

A type \( i \) which represents the type of “individuals”

Function type: \( \alpha \rightarrow \beta \), or \( (\beta)\alpha \) in Church’s notation.

Such a type system is essentially the one used in O’Caml or Haskell.

Addition of type variables; already suggested in R. Gandy’s PhD thesis 1952.
Simple type theory

Two notions of functions: *functional graph* or *program*

How to connect the two notions?

Any functional graph has to determine a program

Description operator $\iota x.\varphi$ and axiom

$$(\exists! x: \alpha) \varphi \rightarrow \varphi(\iota x.\varphi)$$

We then have the “axiom of unique choice”

$$(\forall x: \alpha)(\exists! y: \beta)\psi(x, y) \rightarrow (\exists f: (\beta)\alpha)(\forall x: \alpha)\psi(x, f(x))$$

To use $(\exists! x: \alpha)\varphi$ assumes that we have a notion of *equality* on the type $\alpha$
What is equality in mathematics?

In *set theory*, the axiom of extensionality states that two sets are equal if they have the same(!) elements.
What is equality in mathematics?

In Church’s system we have two forms of the axiom of extensionality.

10° two equivalent propositions are equal

\[(\varphi \equiv \psi) \rightarrow \varphi = \psi\]

10αβ two pointwise equal functions are equal

\[((\forall x : \alpha)\ f(x) = g(x)) \rightarrow f = g\]

Church notices that 10° allows to identify classes with propositional functions.
What is equality in mathematics?

Equality \( x = y \) is defined as

\[(\forall P : \alpha \to o) \ P \ x \to P \ y\]

\( x = y \) is of type \( o \) if \( x \ y \) are of type \( \alpha \)

\( \varphi \equiv \psi \) is defined to be \( \varphi \to \psi \land \psi \to \varphi \)

We can rewrite the extensionality axioms

\[(\varphi = \psi) \equiv (\varphi \equiv \psi)\]

\[(f = g) \equiv ((\forall x : \alpha) \ f(x) = g(x))\]
What is equality in mathematics?

In Church’s system equality \( x = y \) is defined as

\[
(\forall P : \alpha \rightarrow o) \ P \ x \rightarrow P \ y
\]

Henkin, and then P. Andrews, gave alternative presentations of type theory taking equality as primitives

Cf. Lambek and Scott “Introduction to Higher-Order Categorical Logic”
What is equality in mathematics?

One can *justify* these axioms by *defining* equality by induction on the types.

In set theory, one can also interpret the extensionality axiom.

Can we justify/explain the operation $\iota x. \varphi$?
How to “explain” logical laws

1908 Russell *Mathematical Logic as Based on the Theory of Types*

1940 Church *A Formulation of the Simple Theory of Types*

1973 Martin-Löf *An Intuitionistic Theory of Types: Predicative Part*

(Curry, de Bruijn, Howard, Tait, Scott, Martin-Löf, Girard, …)

To consider *propositions* as *types*
How to “explain” logical laws

This “explains” some logical laws such as

modus-ponens: from \( A \rightarrow B \) and \( A \) we can deduce \( B \)

introduction: if we can deduce \( B \) from \( A \) we can deduce \( A \rightarrow B \)

This reduces the problem of proof-checking to the problem of type-checking

Introduction of dependent type \( B (x : A) \) and dependent product \( (\Pi x : A)B \)
and dependent sum \( (\Sigma x : A)B \)
In type theory and therefore in Univalent Foundations the fundamental notion is that of a dependent function, not of a “straight” function, and this is what makes the whole system successful.
We can also introduce a notion of “disjoint sum”

The elements are \( \text{inl}(a) \) with \( a \) in \( A \) or \( \text{inr}(b) \) with \( b \) in \( B \)

We can define function by cases

We can also introduce data types like the type of natural numbers

This strengthens the connection with programming languages

\textit{constructors} corresponds to \textit{introduction rules}
Type of propositions

A proposition is a (special kind of) type

For the type of proposition we need a “type of types”

Universe $U$

What is the equality on $U$?

When are two types equal?
Rules for equality

P. Martin-Löf (1973) introduces a primitive notion of equality $\text{Eq}_A(a_0, a_1)$

What are the laws?

Any element is equal to itself $1_a : \text{Eq}_A(a, a)$

Leibnitz’s law $C(a)$ implies $C(x)$ if $p : \text{Eq}_A(a, x)$
Univalent Foundation and Constructive Mathematics

Rules for equality

New law

\[ J(d) : (∏x_0 x_1 : A)(Πp : Eq_A(x_0, x_1))C(x_0, x_1, p) \]

given \( d : (∏x : A)C(x, x, 1_x) \)

Computation rule: \( J(d) x x 1_x = d x \)

This generalizes

\[(∀x y)Eq_A(x, y) → C(x, y) \text{ given } (∀x)C(x, x) \]

Strengthening similar to the one for existence and disjunction
Other formulation

\[ J'(d) : (\Pi x : A)(\Pi p : Eq_A(a, x))C(x, p) \]

given \( d : C(a, 1_a) \)

Computation rule: \( J'(d) \ a \ 1_a = d \)

This generalizes

\[ (\forall x)Eq_A(a, x) \rightarrow C(x) \] given \( C(a) \)

**Problem:** are these two formulations equivalent?
The singleton law

A.k.a. the “vacuum cleaner power chord principle”

The type $S_a = (\Sigma x : A)\text{Eq}_A(a, x)$ has for element $(x, p)$ with $p : \text{Eq}_A(a, x)$

In particular it has for element $(a, 1_a)$

**Singleton Law** $(\Pi z : S_a)\text{Eq}_{S_a}((a, 1_a), z)$

This follows from the first formulation, and this implies the second formulation

(The fact that the two formulations are equivalent was considered to be a tricky result before work on univalent foundations)

*New* logical law for equality (unknown until 1973)!
The singleton law

“Indeed, to apply Leray’s theory I needed to construct fibre spaces which did not exist if one used the standard definition. Namely, for every space $X$, I needed a fibre space $E$ with base $X$ and with trivial homotopy (for instance contractible). But how to get such a space? One night in 1950, on the train bringing me back from our summer vacation, I saw it in a flash: just take for $E$ the space of paths on $X$ (with fixed origin $a$), the projection $E \to X$ being the evaluation map: path $\mapsto$ extremity of the path. The fibre is then the loop space of $(X, a)$. I had no doubt: this was it! ... It is strange that such a simple construction had so many consequences.”
Stratification of types

As soon as we introduce $\text{Eq}_A(x, y)$ as a type we can iterate this operation

$\text{Eq}_{\text{Eq}_A(x, y)}(p, q)$

A type $A$ is a *proposition*

$(\Pi x_0 \ x_1 : A)\text{Eq}_A(x_0, x_1)$

A type $A$ is a *set*

$(\Pi x_0 \ x_1 : A)\text{prop}(\text{Eq}_A(x_0, x_1))$

a.k.a $\text{UIP}(A)$ “Uniqueness of Identity Proof”

Question (around 1991): is any type a set?
Stratification of types

It seems possible to show

$$(\Pi \, x : A)(\Pi \, p : Eq_A(x, x))Eq(1_x, p)$$

and it is instructive to understand where is the problem with this

This statement is actually *equivalent* to $\text{UIP}(A)$
Stratification of types

$N_1$ is a proposition

$N_0$ is a proposition
Stratification of types

\( A \) is a groupoid

\((\Pi_{x_0} x_1 : A) \text{set}(\text{Eq}_A(x_0, x_1))\)

**Theorem:** any type satisfies the groupoid laws

Follows from the singleton law

**Application:** \( \text{UIP}(A) \) iff each \( \text{Eq}_A(a, a) \) has one element
Stratification of types

**Theorem:** any function $f : A \to B$ satisfies the functorial laws

Any $f : A \to B$ defines

$pMap(f) : \text{Eq}_A(a_0, a_1) \to \text{Eq}_B(f \ a_0, f \ a_1)$

We can define $2$-groupoids, $3$-groupoids, $\ldots$

*Type theory appears to be a generalization of set theory*
Properties of Equality

\[ 1_a : \text{Eq}_A(a, a) \]

\[ \text{transp} : C(a) \rightarrow \text{Eq}_A(a, x) \rightarrow C(x) \]

\[ \text{Eq}_{C(a)}(\text{transp } u \ 1_a, u) \]

\[ \text{Eq}_{(\Sigma x : A)\text{Eq}_A(a, x)}((a, 1_a), (x, p)) \]

Univalence Axiom
Let $N_k$ be the data type with $k$ element

Let $N$ be the data type of natural numbers

The type $N_0$ represents the empty type/the absurd proposition

Let $\neg A$ be the type $A \rightarrow N_0$

We say that $A$ is “decidable” $A + \neg A$

A type $A$ is discrete if each type $\text{Eq}_A(x, y)$ is decidable

**Proposition:** The types $N_k$ and the type $N$ are discrete
Hedberg’s Theorem

**Theorem:** (Hedberg, 1996) *Any discrete type is a set*

**Lemma:** *If we have an operation \( f \ p : \text{Eq}_A(x, y) \) for \( p : \text{Eq}_A(x, y) \) then \( \text{Eq}(f \ p, (f \ 1) \cdot p) \) for any \( p : \text{Eq}_A(x, y) \)*

**Lemma:** *If \( C \) is decidable we can define \( f : C \to C \) with a proof of \( (\Pi x \ y : C')\text{Eq}_C(f \ x, f \ y) \)*

Given extensionality we can weaken the hypothesis to

\[ \neg\neg C \to C \]

instead of \( C \) decidable
Constructive mathematics

$N_2, N$ are sets

With one universe, we can show that they are not propositions

SSReflect considers only decidable structures because of this result

If $A$ is a set we will see later that we have

$$\text{Eq}_{(\Sigma x:A)B}((a, b_0), (a, b_1)) \rightarrow \text{Eq}_{B(a)}(b_0, b_1)$$

but this implication may fail if $A$ is not a set
Voevodsky gives a simple and uniform notion of equivalence between two types

If $A$ and $B$ are sets, this gives the notion of bijection

If $A$ and $B$ are propositions, this gives the notion of logical equivalence

If $A$ and $B$ are groupoids, this gives the notion of categorical equivalence of groupoids
Equivalence

If \( f : A \to B \) the fiber of \( f \) at \( b : B \) is the type

\[
F(b) = (\Sigma x : A)\text{Eq}_B(b, f \ x)
\]

\( f \) is an equivalence iff this fiber is \textit{contractible} at each point \( b \)

\( \text{prop}(F(b)) \times F(b) \)

We write \( A \simeq B \) for \((\Sigma f : A \to B)\text{Equiv}(f)\)

**Proposition:** \textit{The identity function on any type is an equivalence}

This is not trivial!
Univalent Foundation and Constructive Mathematics

Equivalence

If \( g : C \to D \) is an equivalence we have a proof of \((\Pi d : D)F(d)\)

Hence there exists a function \( h : D \to C \) which is a section of \( g \)

\((\Pi x : D)\text{Eq}_B(x, g(h x))\)
Univalence Axiom

Since $X \simeq X$ we have a map $\text{Eq}_U(A, B) \to A \simeq B$

The Univalence Axiom states that this map is an equivalence

In particular we have

$A \simeq B \to \text{Eq}_U(A, B)$

This generalizes Church’s axiom of extensionality for propositions

**Lemma:** If $A$ and $B$ are two propositions and $B \to A$ then any map $A \to B$ is an equivalence

This will be proved later
Univalence Axiom

We have $\text{Eq}_U(A, B)$ if $A$ and $B$ are equivalent propositions.

We can hope closer connections to HOL and to the SSReflect style of doing proofs (equational reasoning).

E.g. $\text{Eq}_A(a_0, a_1) \rightarrow \text{Eq}_A(u_0, u_1) \rightarrow \text{Eq}_U(\text{Eq}_A(a_0, u_0), \text{Eq}_A(a_1, u_1))$
The Univalence Axiom implies that two isomorphic sets are equal.

It also implies that two equivalent groupoids are equal.

Voevodsky has shown that this axiom implies *function extensionality*.

From now on, we shall work with Univalence and hence function extensionality.
Equivalence

We say that \( g : B \to A \) is a section of \( f : A \to B \) iff \( \text{Eq}(f \circ g, \text{id}_B) \)

We say that \( f \) is a retraction of \( g \) iff \( \text{Eq}(g \circ f, \text{id}_A) \)

\( f \) and \( g \) are inverse iff \( g \) is a section of \( f \) and \( f \) a retraction of \( g \)
Graduate Lemma: If $f$ and $g$ are inverse then $f$ is an equivalence.

Given this we can prove e.g.

Lemma: If $A$ and $B$ are two propositions and $B \rightarrow A$ then any map $A \rightarrow B$ is an equivalence.
Equivalence

The proof of the Graduate Lemma consists itself in several Lemmas

**Lemma 1:** If \( f : A \to B \) has a left inverse \( g \) then \( \text{prop}(B) \) implies \( \text{prop}(A) \)

**Lemma 2:** If \( f \) has a left inverse, then
\[
p\text{Map}(f) : \text{Eq}_A(a_0, a_1) \to \text{Eq}_B(f \ a_0, f \ a_1)
\]
has a left inverse

**Lemma 3:** If we have a family of maps \( \varphi_x : D(x) \to E(x) \) and for all \( x : A \), the map \( \varphi_x \) has a left inverse then the map
\[
(\Sigma x : A)D(x) \to (\Sigma x : A)E(x)
\]
\[
(x, d) \mapsto (x, \varphi_x \ d)
\]
has a left inverse
Any involutive function is an equivalence

\( \neg: N_2 \to N_2 \) is an equivalence

We need function extensionality to prove \( \neg \circ \neg = \text{id}_{N_2} \)

Hence we have a proof of \( \text{Eq}_U(N_2, N_2) \) which is not the reflexivity

By univalence \( \text{Eq}(\text{Eq}_U(N_2, N_2), \text{Equiv}(N_2, N_2)) \)

Hence \( U \) is not a set

It can be shown that \( U_1 \) is not a groupoid, \( U_2 \) is not a 2-groupoid and so on
Applications

Axiom of “choice”

$$\text{Eq}_U((\Pi x : A)(\Sigma y : B)C(x, y), (\Sigma f : A \rightarrow B)(\Pi x : A)C(x, f \ x))$$

Distributivity law

$$\text{Eq}_U((\Sigma x : A)(B + C), (\Sigma x : A)B + (\Sigma x : A)C)$$

Induction principle

$$\text{Eq}_U((\Pi z : A + B)C(z), (\Pi x : A)C(\text{inl}(x)) \times (\Pi y : B)C(\text{inr}(y)))$$
We have

\[ \text{Eq}_U(A \times B, B \times A) \]

\[ \text{Eq}_U(A \times (B \times C), (A \times B) \times C) \]

\[ \text{Eq}_U(A \times N_1, A) \]

This is less surprising than it seems however

\[ A \times B \text{ is } \text{not} \text{ convertible to } B \times A \]
Univalence Axiom

We have $\text{Eq}_U(N, N + N_1)$

Notice that this is *not* true in set theory

$0$ belongs to $N$ but not to $N + N_1$

*a type structure is a “syntactical discipline for enforcing level of abstraction”*  
Reynolds 1983

$0 : N$ is a *judgement* and not a *type* (using Martin-Löf terminology)

This can already be found in the design of Automath (1967)
A family of types over \( A \) can be seen as a function \( A \to U \).

The map

\[ \text{Eq}_U(A, B) \to A \simeq B \]

gives for each \( p : \text{Eq}_U(A, B) \) a map

\[ \lambda x.\text{transp}\ x\ p : A \to B \]

and the transport of a family \( C : A \to U \) can be seen as the composition of this map and \( \text{pMap}(C') \)
Induction Principle for equivalences

If we have a statement $P(B, f)$ for

$B : U, \ f : A \to B, \ p : \text{isEquiv}(A, B, f)$

For proving that $P(B, f)$ holds universally, it is enough to prove $P(A, \text{id}_A)$

This follows from univalence and the singleton law
Application

E.g. define the type of pointed types $Pt = (\Sigma X : U)X$

If $f : A \to B$ equivalence and $Eq_B(f \ a, b)$ then

$Eq_{Pt}((A, a), (B, b))$
Consider now the type $\text{Fam} = (\Sigma X : U)X \to U$

This is the type of “families” $(X, F)$ with $F : X \to U$

If $f : A \to B$ equivalence and $C : B \to U$ then

$\text{Eq}_{\text{Fam}}((A, C \circ f), (B, C'))$

Hence

$\text{Eq}_U((\Sigma x : A)C(f \ x), (\Sigma y : B)C(y))$

and

$\text{Eq}_U((\Pi x : A)C(f \ x), (\Pi y : B)C(y))$
Back to the stratification

Using function extensionality we can show $\text{prop}(\neg A)$ for any type $A$. 
Using function extensionality, we can prove

**Theorem:** *If we have* \((\Pi x : A) \text{prop}(B)\) *then* \(\text{prop}((\Pi x : A)B)\)

\(A\) *can be any type in this statement*

This is similar to impredicativity: any product of propositions is a proposition

What about a product of sets?
We have a notion of *property*: family of propositions over a type.

To be an equivalence is a property of a function.

The axiom of univalence is a proposition.

Essential difference between *property* and *structure*.

E.g. $f : A \to B$ isomorphism is a structure in general.

and a property if $A$ and $B$ are sets.

E.g. to be discrete is a property of a set, and hence a property of a type.
Back to the stratification

If $P$ is a proposition and $x \ y : P$, is $\text{Eq}_P(x, y)$ a proposition?

**Lemma:** If $A$ is a type and we have $\varphi : (\Pi x : A)\text{Eq}_A(a, x)$ then

$$(\Pi u : A)(\Pi p : \text{Eq}_A(x, u))\text{Eq}(p \cdot (\varphi u), \varphi x)$$

Direct from the singleton law and the groupoid laws
Corollary: If $P$ is a proposition and $x, y : P$ then $\text{Eq}_P(x, y)$ is contractible

$Q$ contractible means $\text{prop}(Q) \times Q$, and this is a proposition
Back to the stratification

In particular any proposition is a set

Any set is a groupoid

Voevodsky’s stratification is cumulative
To be a proposition, a set, ... is a property

To prove

\[(\Pi u \; v : \text{prop}(A)) \text{Eq}(u, v)\]

we use that \(\text{prop}(A) \to \text{set}(A)\) and function extensionality

By function extensionality, \(\text{set}(A)\) is a proposition as well
Back to the stratification

\(N_0\) is a proposition
\(N_1\) is contractible
\(N_2, N_3, \ldots\) and \(N\) are sets (by Hedberg’s Theorem)

With a universe one can prove that they are \textit{not} propositions
Equality in a sigma type

If $B(x) \ (x : A)$ is a family of type and $p : \text{Eq}_A(a_0, a_1)$ we can define

$$B(a_0) \to B(a_1)$$

$b \mapsto \text{transp} \ b \ p$

We have

$$\text{Eq}_U(\text{Eq}_{(\Sigma x : A) B}((a_0, b_0), (a_1, b_1)), (\Sigma p : \text{Eq}_A(a_0, a_1)) \text{Eq}_{B(a_1)}(\text{transp} \ b_0 \ p, b_1))$$
Equality in a sigma type

We have

\[
\text{prop}(A), \ (\Pi x : A)\text{prop}(B) \rightarrow \text{prop}((\Sigma x : A)B)
\]

\[
\text{set}(A), \ (\Pi x : A)\text{set}(B) \rightarrow \text{set}((\Sigma x : A)B)
\]

In particular

\[
\text{prop}(A), \ (A \rightarrow \text{prop}(B)) \rightarrow \text{prop}(A \times B)
\]

\[
\text{prop}(A) \times A \text{ is a proposition}
\]
Equality in a sigma type

It follows that “to be contractible”

\[ \text{prop}(A) \times A \]

is a proposition

It then follows by extensionality that to be an equivalence is a property

We have \( \text{Eq}_U(\text{prop}(A) \times A, \text{Eq}_U(A, N_1)) \)

In particular \( A \) is contractible iff \( \text{Eq}_U(A, N_1) \)
Equality in a sigma type

If $A$ is a set and

$$\text{Eq}_{\Sigma x:A} B(x)((a, b_0), (a, b_1))$$

then

$$\text{Eq}_{B(a)}(b_0, b_1)$$

This is because $\text{Eq}_A(a, a)$ is a proposition.
Equality in a sigma type

We say that $g : C \to D$ is an embedding iff

$$pMap(g) : Eq_C(x, y) \to Eq_D(g \cdot x, g \cdot y)$$

is an equivalence

This is a property of $g$

If $C$ and $D$ are sets, this is the same as being injective

$$Eq_D(g \cdot x, g \cdot y) \to Eq_C(x, y)$$
Equality in a sigma type

Proposition: If $B(x)$ is a family of propositions over a type $A$ then the first projection $(\Sigma x : A)B \rightarrow A$ is an embedding

If $A$ is a set we can think of $(\Sigma x : A)B$ as the subset of elements in $A$ satisfying $B$

Cf. definition of subset in Bishop’s mathematics
Applications

Given $A$

There are two notions of family of types on $A$

$A \to U$ and $\text{Slice}(A) = (\Sigma X : U)X \to A$

Any $F : A \to U$ defines a pair

$u(F) = (\Sigma x : A)F x, (\lambda z) z.1$

in $\text{Slice}(A)$

**Theorem:** The map $u : (A \to U) \to \text{Slice}(A)$ is an equivalence
If $A, B : U$ we can define $T : N_2 \rightarrow U$ by

$$T \ 0 = A \quad T \ 1 = B$$

**Proposition:** We have $\text{Eq}_U(A + B, (\Sigma x : N_2)T \ x)$

This implies e.g. that $A + B$ is a set if $A$ and $B$ are sets.
Lemma: The canonical map (and actually any map)

\[ \text{Eq}_{(\Pi x : A) B}(f, g) \rightarrow (\Pi x : A)\text{Eq}_B(f x, g x) \]

is an equivalence

The proof is incredible
Product of sets?

Let \( C = (\Pi x : A)B \)

We notice that both

\[
(\Sigma g : C)\text{Eq}_C(f, g) \quad \text{and} \quad (\Sigma g : C)(\Pi x : A)\text{Eq}_B(f \ x, g \ x)
\]

are contractible

By "choice"

\[
\text{Eq}_U((\Sigma g : C)(\Pi x : A)\text{Eq}_B(f \ x, g \ x), (\Pi x : A)(\Sigma y : B)\text{Eq}_B(f \ x, y))
\]

**Corollary:** The product of any family of sets is a set
**Lemma:** if we have a family of maps $\varphi_x : D(x) \to E(x)$ for $x : C$ and the total map $(x, b) \mapsto (x, \varphi_x b)$ is an equivalence then each map $\varphi_x$ is an equivalence

This is a standard lemma in the theory of fibrations in homotopy theory

E.g. P. May *A concise course in algebraic topology*
Product of sets?

The proof is a sequence of equality, where \( F = (\sum x : C)D \) and \( G = (\sum x : C)E \)

\[
(\sum (x, d) : F)\text{Eq}((x_0, e_0), (x, \varphi_x d))
\]

\[
(\sum x : C)(\sum d : D(x))(\sum p : \text{Eq}_C(x_0, x))\text{Eq}_{E(x)}(\text{transp } e_0 p, \varphi_x d)
\]

\[
(\sum x : C)(\sum p : \text{Eq}_C(x_0, x))(\sum d : D(x))\text{Eq}_{E(x)}(\text{transp } e_0 p, \varphi_x d)
\]

\[
(\sum u : N_1)(\sum d : D(x_0))\text{Eq}_{E(x_0)}(e_0, \varphi_{x_0} d)
\]

\[
(\sum d : D(x_0))\text{Eq}_{E(x_0)}(e_0, \varphi_{x_0} d)
\]
Set mathematics

What is a poset?

It should be a set $A$

with a relation $R : A \to A \to U$ such that $\text{prop}(R x y)$

d this relation should be reflexive and transitive

and we have $\text{Eq}_U(\text{Eq}_A(x, y), R x y \times R y x)$
Set mathematics

What is a group?

It should be a set $A$

with some operations

$m : A \to A \to A \quad \text{inv} : A \to A \quad e : A$

and the usual axioms

We can form the type of all groups
Let $\text{Grp}(A)$ be the type of structures of groups over the set $A$.

If $f : A \to B$ is a bijection between the sets $A$ and $B$,
then we have $\text{Eq}_U(A, B)$ by univalence.

Hence we have a map $\text{Grp}(A) \to \text{Grp}(B)$.

Any group structure on $A$ can be *transported* into a group structure on $B$
along the bijection $f$. 

**Transport of structures**
Transport of structures

On the other hand there is a direct notion of transport of operations

\[ m_B b b' = f (m_A (g b) (g b')) \quad \text{inv}_B b = f (\text{inv}_A (g b)) \quad e_B = f e_A \]

where \( g \) is the inverse of \( f \)

The two notions of transport coincide

In particular, we get in this way that \( B \) satisfies the axioms of group with operations \( m_B, \text{inv}_B, e_B \)
The collection of binary sequences form a set because we know what it means for two binary sequences to be equal. Given two groups, or sets, on the other hand, it is generally incorrect to ask if they are equal; the proper question is whether or not they are isomorphic.
Structures

The collection of all groups

\[ \text{Group} = (\Sigma X : U)\text{set}(X) \times \text{Grp}(X) \]

form a groupoid

**Theorem:** The map \( \text{Eq}_{\text{Group}}(g_0, g_1) \to \text{Iso}(g_0, g_1) \) is an equivalence

In particular, two isomorphic groups are “equal”
We add $A : U_0$ if $A$ is a type and $\text{prop}(A)$

With the resizing rule, the system becomes *impredicative*
Voevodsky also requires that the collection of all propositions is a small type (which will be a small set)

For expressing this, we introduce a type $\Omega : U_0$ with the rules

$$(A, p) : \Omega \text{ if } A \text{ is a type and } p : \text{prop}(A)$$

If $X : \Omega$ then $X.1 : U_0$ and $X.2 : \text{prop}(X.1)$

**Theorem:** $\Omega$ is a set

The collection of sets form a topos with $\Omega$ as the set of truth-values
Propositional truncation

Using the resizing rule, Voevodsky defines the operation

$$\text{inh}(A) = (\Pi X : U)\text{prop}(X) \to (A \to X) \to X$$

What is important is

1. $\text{inh}(A)$ is a proposition
2. $A \to \text{inh}(A)$
3. $\text{inh}(A) \to \text{prop}(X) \to (A \to X) \to X$

Intuitively $\text{inh}(A)$ is a proposition expressing that $A$ is inhabited

If $A$ is a proposition we have $\text{Eq}_U(A, \text{inh}(A))$
We can define new connectives

$$(\exists x : A)B \text{ defined as } \text{inh}(\Sigma x : A)B$$

$$A \lor B \text{ defined as } \text{inh}(A + B)$$

These connectives are similar to (but different from) the corresponding connectives in topos theory

**Lemma:** If $A$ and $B$ are incompatible propositions then $\text{Eq}_U(A + B, A \lor B)$

In particular, $A + B$ is a proposition in this case

$$(\Pi X : U)\text{prop}(X) \rightarrow X + \neg X \text{ is a proposition}$$
Unique Choice

We also have the principle of unique choice, for $C, D$ sets

$$(\forall x : C)(\exists! y : D) \psi(x, y) \rightarrow (\Sigma g : C \rightarrow D)(\forall x : C)\psi(x, g \, x)$$

Without this principle, we would have two notions of functions

Function as $\lambda$-term or as functional relation

For $A$ set and $B$ propositions we have

$$(\exists! x : A)B \rightarrow (\Sigma x : A)B$$

This can be seen as a refinement of Church’s description operator
Constructive mathematics

We can define the *image* of a map \( f : A \to B \)

This is determined by the *property* \( (\exists x : A)\text{Eq}_B(b, f \ x) \) on \( B \)

Compare with the fiber \( (\sum x : A)\text{Eq}_B(b, f \ x) \)

We have a satisfactory correspondance between *subsets* and *properties*
Constructive mathematics

Difference between $\text{inh}(A)$ and $\neg\neg A$

We have $\text{inh}(A) \rightarrow \neg\neg A$

Let $P(n)$ be a family of decidable propositions over $N$

**Proposition:** $\text{inh}((\Sigma n : N)P(n)) \rightarrow (\Sigma n : N)P(n)$

This is remarkable since $(\Sigma n : N)P(n)$ needs not be a proposition

**Theorem:** $\neg\neg((\Sigma n : N)P(n)) \rightarrow (\Sigma n : N)P(n)$ is not provable
No reason any more why countable choice

\[(\forall n : N)(\exists x : X) R(n, x) \rightarrow (\exists f : N \rightarrow X)(\forall n : N) R(n, f \ n)\]

should hold

This is like in topos theory
Constructive mathematics

Definition of quotient by an equivalence relation

Given $A$ a type and $R : A \to A \to U$ a proposition valued family of types which is an equivalence relation we define an equivalence class to be a proposition valued $P : A \to U$ such that

$P$ is inhabited $(\exists x : A) P(x)$

$P x \to P y \to R x y$

$P x \to R x y \to P y$

Notice that from $P$ a given equivalence class we cannot extract in general any element in $A$ satisfying $P$
Universal property

Let $A/R$ the set of equivalence classes

We have a canonical map $s : A \rightarrow A/R$ and $R x_0 x_1 \rightarrow Eq_{A/R}(s x_0, s x_1)$

Let $f : A \rightarrow B$ a map into a set $B$ such that $R x_0 x_1 \rightarrow Eq_B(f x_0, f x_1)$

There exists a unique map $g : A/R \rightarrow B$ such that $g \circ s = f$

And this despite the fact that we cannot extract in general an element in a given equivalence class!
A ring $R$ will be represented as a set with the usual structure

$a$ divides $b$ will be defined as there exists $x$ such that $ax = b$

If $a$ is regular i.e. $au = 0 \rightarrow u = 0$ then this $x$ is uniquely determined and we have an explicit division operation
More example in algebra

An ideal $P$ is a subset of $R$ satisfying the usual laws

The ideal is prime iff $ab \in P \rightarrow a \in P \lor b \in P$

Notice the use of $\lor$

We say that an ideal $I$ is finitely generated iff there exists a finite list $x_1, \ldots, x_n$ which generates $I$

Notice that given $I$ finitely generated we cannot in general extract an explicit list of generators

**Lemma:** If $I \cdot J \subseteq P$ and $P$ is prime then $I \subseteq P$ or $J \subseteq P$
More example in algebra

In general, we can introduce the witness of an existential statement as long as we use this witness to build an object which does not depend on the exact choice of this witness.
An example in analysis

If we define the type of real numbers \( R \) as a quotient of the set of Cauchy sequences of rationals

We can define \( x \# y \) as meaning \( (\exists r > 0) r \leq |x - y| \)

We can define the inverse function \( (\Pi x : R)x \# 0 \rightarrow R \)

This is because the inverse is \textit{uniquely} determined
More example in algebra

Even if we start with a discrete structure, some natural operations build non necessarily discrete structure

E.g. localization of a ring for a multiplicative monoid

What was missing before was the insight that structures in algebra should be represented by sets
Finite sets

Category of finite sets \( N_{k+1} = N_k + N_1 \)

We say that \( X \) is finite iff there exists \( k \) such that \( \text{Eq}_U(X, N_k) \)

\[(\exists k : N)\text{Eq}_U(X, N_k) \text{ is a proposition}\]

If \( X \) is finite, we can extract its cardinality but not the given equality proof \( \text{Eq}_U(X, N_k) \) (there are \( k! \) such proofs)

We use that \( \text{Eq}_U(N_k, N_l) \) implies \( \text{Eq}_N(k, l) \)

If \( X \) has \( k \) elements we have \( \text{inh}(\text{Eq}_U(\text{Eq}_U(X, X), N_k!)) \)

If \( X \) is finite then \( X \) is a discrete set
Torsors

We consider only $\mathbb{Z}$-torsors

A torsor is a set $X$ with a $\mathbb{Z}$-action such that for any $u$ in $X$ the map $n \mapsto u + n$, $\mathbb{Z} \to X$ is an equivalence

and $\text{inh}(X)$

If $X$ is a torsor we cannot in general exhibit one element of $X$

There is always the trivial torsor $\text{triv}$ where $X = \mathbb{Z}$

Theorem: $\text{Eq}_U(\text{Eq}_{\text{Torsor}}(\text{triv}, \text{triv}), \mathbb{Z})$

If $X$ is a torsor we have

$$(\Pi u_0 \ u_1 : X)(\exists! n : \mathbb{Z}) \text{Eq}_X(u_0 + n, u_1)$$

and so, by unique choice we have an application

$$X \times X \rightarrow \mathbb{Z}$$

$$(u_0, u_1) \mapsto u_1 - u_0$$

such that $\text{Eq}_X(u_0 + u_1 - u_0, u_1)$
What about a resizing rule for sets?

We cannot add $A : U_0$ if $A$ is a type and $\text{set}(A)$.

We cannot have

$$T = (\Pi X : U_0) \text{set}(X) \to (((X \to \Omega) \to \Omega) \to X) \to X$$

in $U_0$, since then $\text{Eq}_{U_0}(T, (T \to \Omega) \to \Omega)$ which implies $N_0$.

Cf. Reynolds non set theoretic model of polymorphisms.

So we still need the hierarchy of universe.
Global choice

We have

\( \neg((\Pi X : U)\text{set}(X) \to \text{inh}(X) \to X) \)

which is the negation of the axiom of global choice.

No global choice function is invariant by isomorphism.
Look at the example of the collection of groups

A *category* is given by a type of objects $A$ which should be a *groupoid*

We have $\text{Hom}(a_0, a_1)$ which is a *set*

with the usual operations and laws of composition

We can then define the *set* of isomorphisms $\text{Iso}_A(a_0, a_1)$

We have a map $\text{Eq}_A(a_0, a_1) \to \text{Iso}_A(a_0, a_1)$

This map should be an equivalence (a bijection in this case)
Category theory

Compare with the definition in set theory

Notion of “locally small” category

But this refers to the “size” and not to the complexity of equality
Category theory

We can define the notion of *equivalence* between two categories

We can consider the collection of “all” categories

Two equivalent categories are equal

B. Ahrens, C. Kapulkin, M. Shulman
“Univalent categories and the Rezk completion”
Category theory

The notion of Galois connections between posets

The notion of adjunction between categories
Category theory

Let $F : A \to B$ be a functor between two categories $A$ and $B$.

Like a monotone map at the level of groupoids, $F$ is essentially surjective iff

$\forall b : B \exists a : A \exists! \text{iso}_B(b, F a)$

This is a property of the functor.

$F$ is full and faithful iff the map

$\text{Hom}_A(a_0, a_1) \to \text{Hom}_B(F a_0, F a_1)$

is an equivalence (here a bijection).
Lemma: If $F$ is full and faithful then for any $b$ in $B$ the type

$$(\Sigma a : A) \text{Iso}_B(b, F a)$$

is a proposition.

Corollary: If $F$ is full and faithful and essentially surjective then $F$ is an equivalence of categories.

We use the principle of unique choice at the level of groupoids!
Univalent Foundation and Constructive Mathematics

Category theory

This definition of category solves some foundational issues that are somewhat disturbing when category theory is formulated in set theory.

For instance, what should be a *cartesian* category (i.e. category with binary product)?

Should the product of two objects given explicitly as a function?

We have two notions (if we don’t assume choice)
In the univalent foundation, there is no problem since the product of two objects is uniquely determined up to isomorphism.

And hence *up to equality* by definition of category.

Since we have unique choice, we have an explicit product function on objects.
Beyond groupoids

$U_0$ is not a set

$U_1$ is not a groupoid

For 2-groupoids new phenomena arise

E.g. Eckmann-Hilton

\[ \text{Eq}_{\text{Eq}_A(x,x)(1_x,1_x)}(\alpha \cdot \beta, \beta \cdot \alpha) \]
