Hybrid Systems

- Usual representation: Hybrid Automata

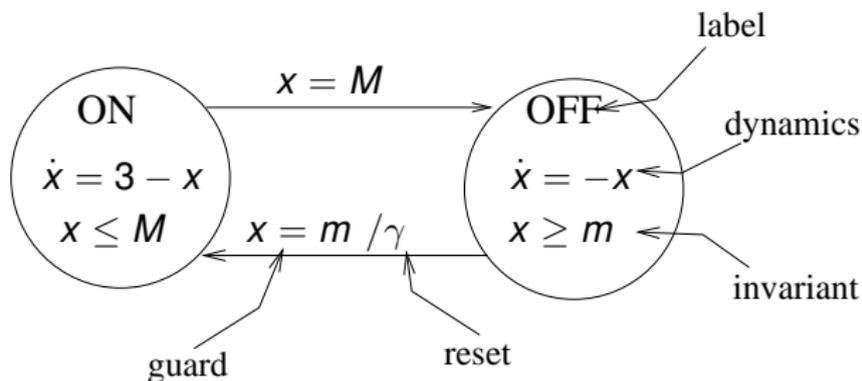

In general, we can have *differential inclusions* instead of differential equations

Hybrid Systems

Polygonal Hybrid Systems (SPDIs)

- A finite partition of the plane into convex polygonal sets
- Dynamics given by the angle determined by two vectors:

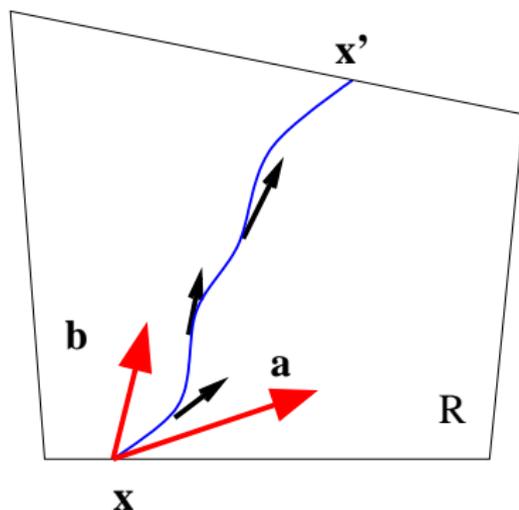

$$\dot{x} \in \angle_{\mathbf{a}}^{\mathbf{b}}$$

Polygonal Hybrid Systems (SPDIs)

- A finite partition of the plane into convex polygonal sets
- Dynamics given by the angle determined by two vectors:

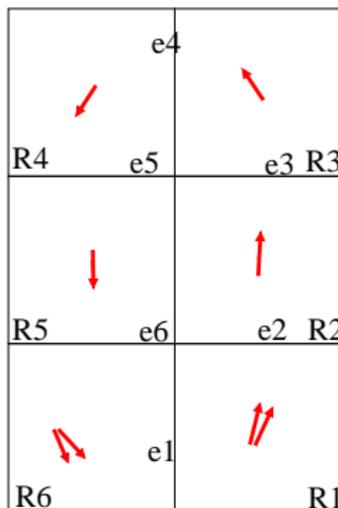

$$\dot{x} \in \angle_{\mathbf{a}}^{\mathbf{b}}$$

Polygonal Hybrid Systems (SPDIs)

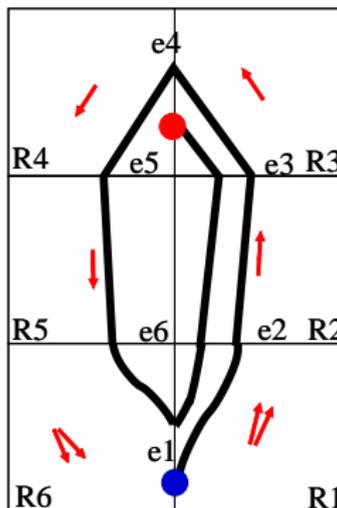

- A finite partition of the plane into convex polygonal sets
- Dynamics given by the angle determined by two vectors:

$$\dot{x} \in \angle_{\mathbf{a}}^{\mathbf{b}}$$

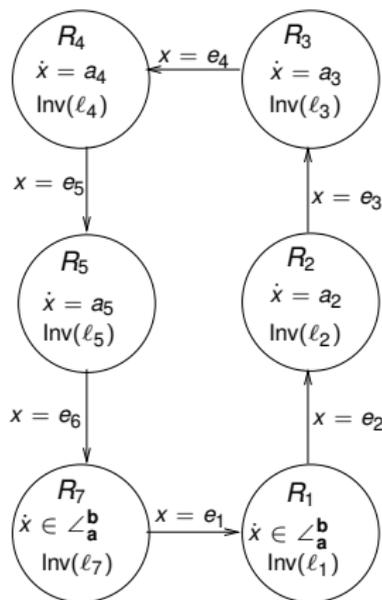

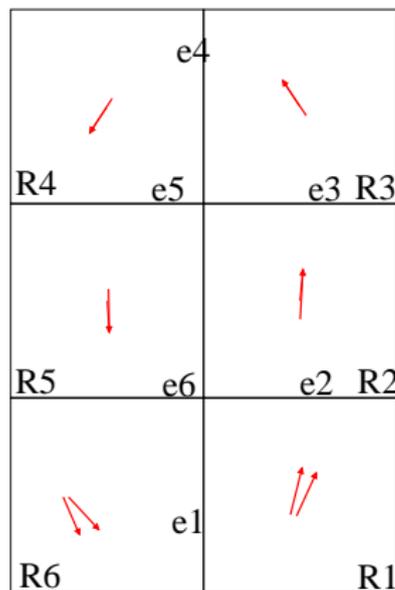

Polygonal Hybrid Systems (SPDs)

- A finite partition of the plane into convex polygonal sets
- Dynamics given by the angle determined by two vectors:
 $\dot{x} \in \angle_{\mathbf{a}}^{\mathbf{b}}$

Polygonal Hybrid Systems (SPDIs)

- An SPDI can be seen as a hybrid automaton

Polygonal Hybrid Systems (SPDIs)

Underlying Graph

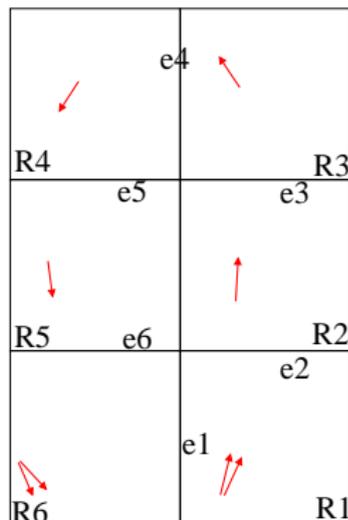

- The reachability algorithm operates on a graph representation, not on the automaton

Polygonal Hybrid Systems (SPDs)

Underlying Graph

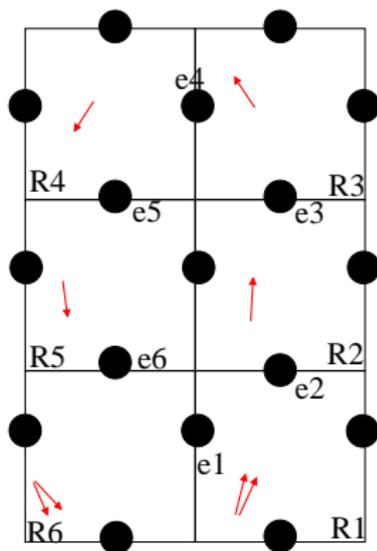

- The reachability algorithm operates on a graph representation, not on the automaton

Polygonal Hybrid Systems (SPDs)

Underlying Graph

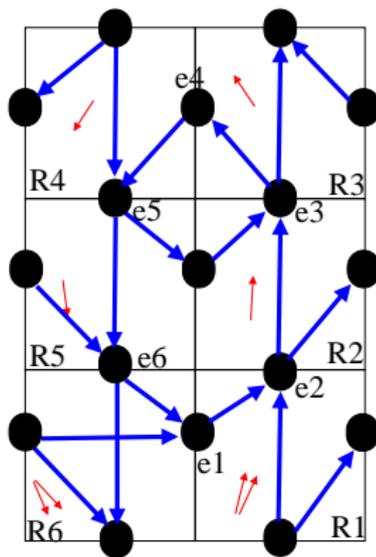

- The reachability algorithm operates on a graph representation, not on the automaton

Underlying Graph

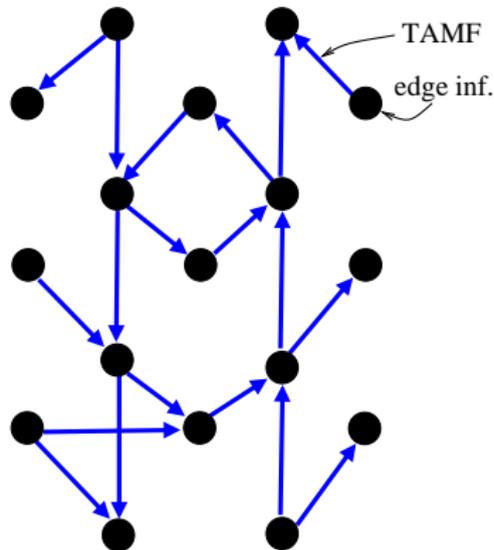

- The reachability algorithm operates on a graph representation, not on the automaton

Polygonal Hybrid Systems (SPDs)

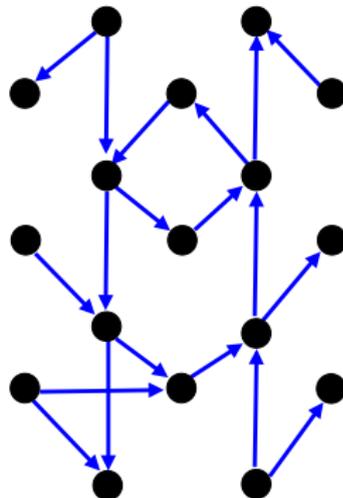

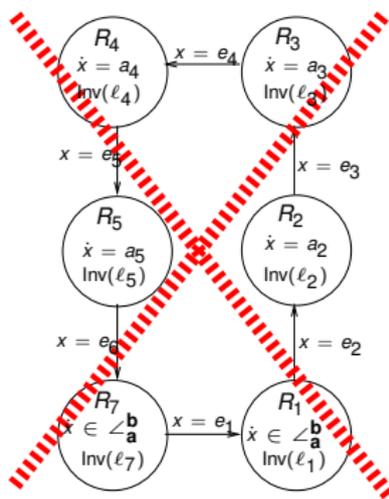

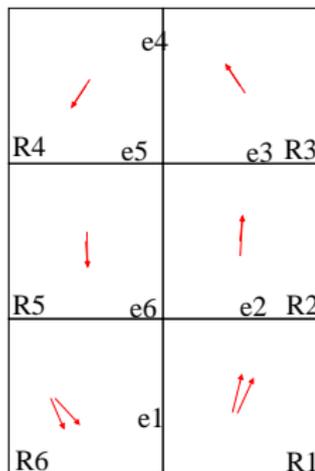

Underlying Graph

- The reachability algorithm operates on a graph representation, not on the automaton

Polygonal Hybrid Systems (SPDs)

Three Views

- We will, however, use the geometrical representation in what follows instead for clarity of presentation

Known Results about SPDIs

- Reachability is decidable –in the plane
(based on Poincaré maps, finite characterization of simple cycles, acceleration, ...)
 - DFS algorithm (HSCC'01)
 - BFS algorithm (VMCAI'04)
 - Tool: SPeeDI (CAV'02)
- Reachability is undecidable –3-dim and higher (ICALP'94)
- For slight extensions in 2-dim reachability is an open question, for others is undecidable (CONCUR'02, FSTTCS'05)
- Phase portrait computation
 - Viability and controllability kernels (HSCC'02)
 - Invariance kernels (NJC'04)

Few Preliminaries

- We only need to consider simple cycles
 - Given a sequence of non-repeating edges (except for the first and last edge) – e.g., $\sigma = e_1, \dots, e_k, e_1$
 - Consider the polygonal subset of the SPDI determined by such sequence (denoted K_σ)

Few Preliminaries

 - Consider the polygonal subset of the SPDI determined by such sequence (denoted K_σ)

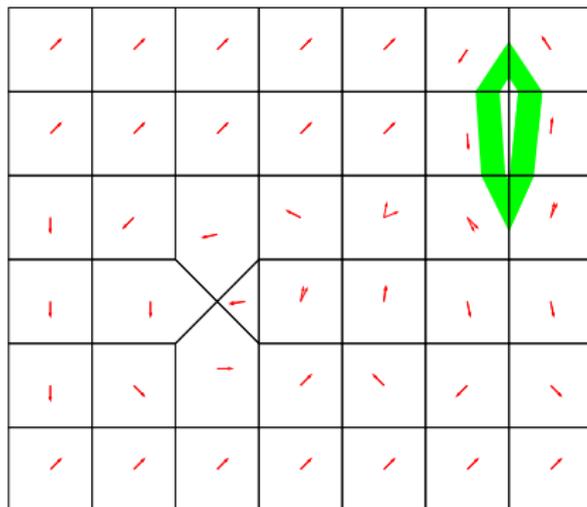

Controllability Kernels

- Given K_σ , its **controllability kernel** is the largest subset such that any two points are reachable from each other

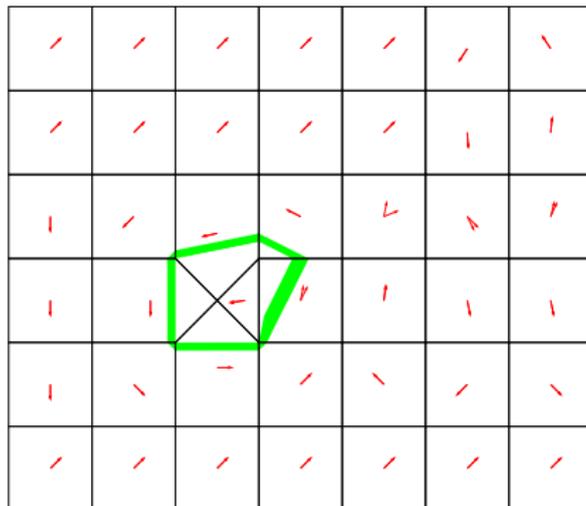

Controllability Kernels

- Given K_σ , its **controllability kernel** is the largest subset such that any two points are reachable from each other

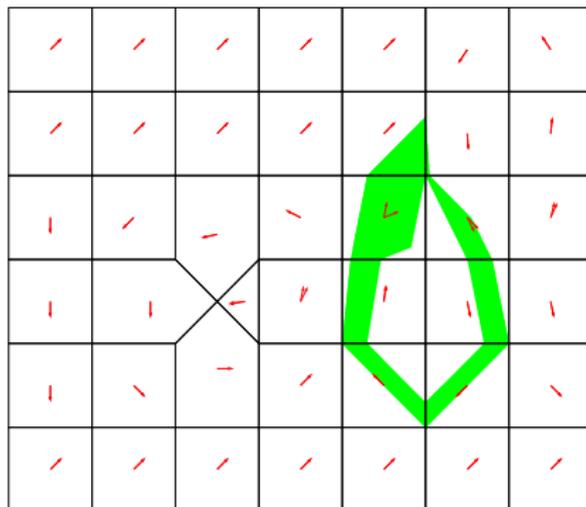

Controllability Kernels

- Given K_σ , its **controllability kernel** is the largest subset such that any two points are reachable from each other

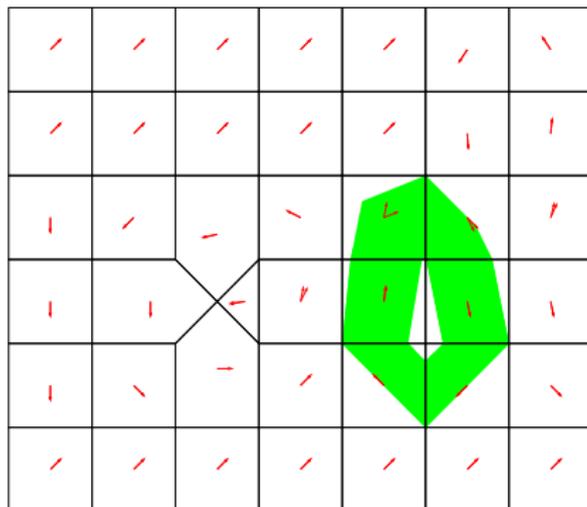

Controllability Kernels

- Given K_σ , its **controllability kernel** is the largest subset such that any two points are reachable from each other

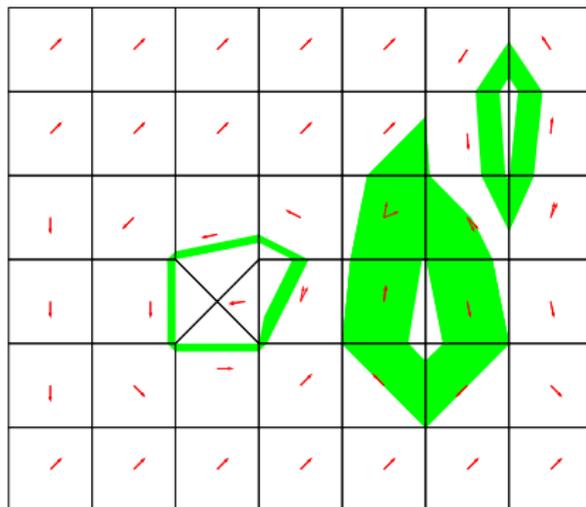

Controllability Kernels

- Given K_σ , its **controllability kernel** is the largest subset such that any two points are reachable from each other

Controllability Kernels

- Given K_σ , its **controllability kernel** is the largest subset such that any two points are reachable from each other

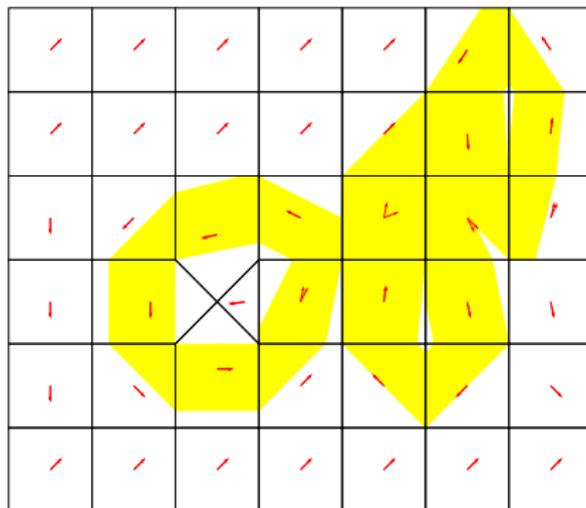

Viability Kernels

- Given K_σ , its **viability kernel** is the largest subset such that for any point in the set, there is at least one trajectory which remains in the set forever

Viability Kernels

- Given K_σ , its **viability kernel** is the largest subset such that for any point in the set, there is at least one trajectory which remains in the set forever

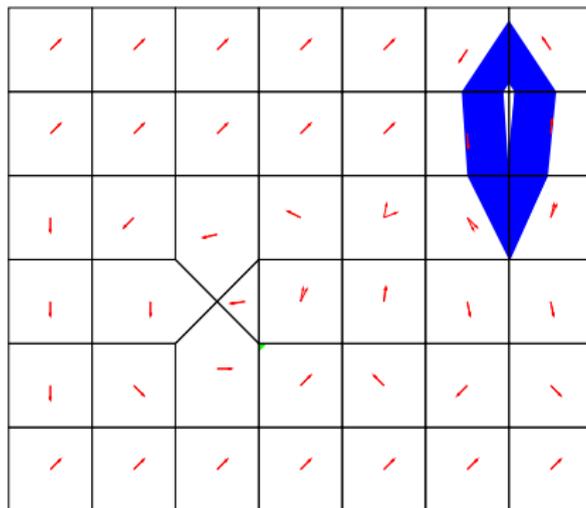

Invariance Kernels

- Given K_σ , its **invariance kernel** is the largest subset such that for any point x in the set, there is at least one trajectory starting in it and every trajectory starting in x is viable

Invariance Kernels

- Given K_σ , its **invariance kernel** is the largest subset such that for any point x in the set, there is at least one trajectory starting in it and every trajectory starting in x is viable

Semi-Separatrices

- A **semi-separatrix** is a closed curve dissecting the state space into two subsets such that one is reachable from the other but not vice-versa

Semi-Separatrices

- A **semi-separatrix** is a closed curve dissecting the state space into two subsets such that one is reachable from the other but not vice-versa

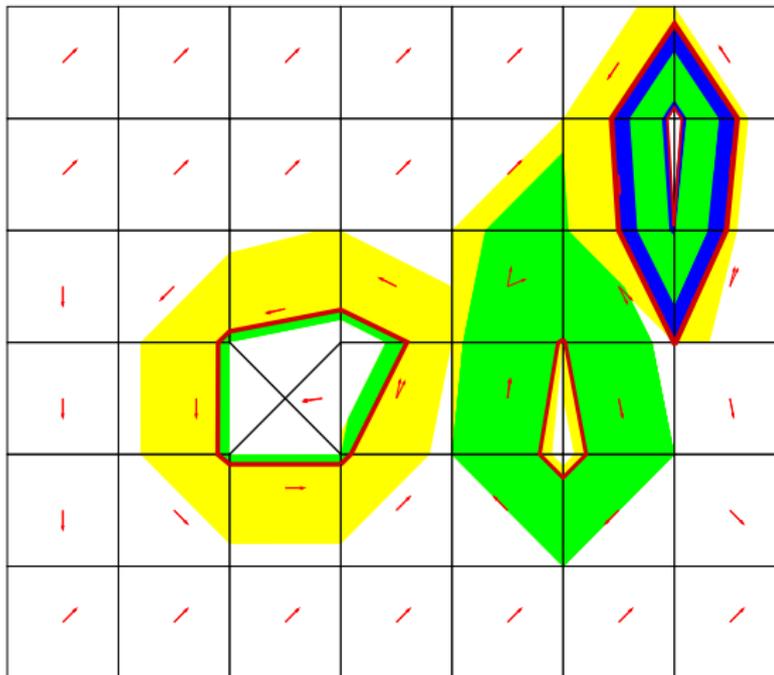

Semi-Separatrices

Based on properties of limit trajectories on simple cycles and the invariance kernel we have an algorithm for computing semi-separatrices

Theorem

The computation of semi-separatrices for SPDIs is decidable

State-Space Reduction using Semi-Separatrices

Let e be a source edge and e' a target edge

- Identification of *inert* edges
 - Given a semi-separatrix γ , e_l is **inert** if it lies outside γ while e lies inside, or it lies inside, while e' lies outside

Theorem

Given an SPDI \mathcal{S} , a semi-separatrix γ , and edges e and e' , then, e' is reachable from e in \mathcal{S} if and only if e' is reachable from e in \mathcal{S} without the inert edges

State-Space Reduction using Semi-Separatrices

Let e be a source edge and e' a target edge

- Identification of *inert* edges
 - Given a semi-separatrix γ , e_l is **inert** if it lies outside γ while e lies inside, or it lies inside, while e' lies outside

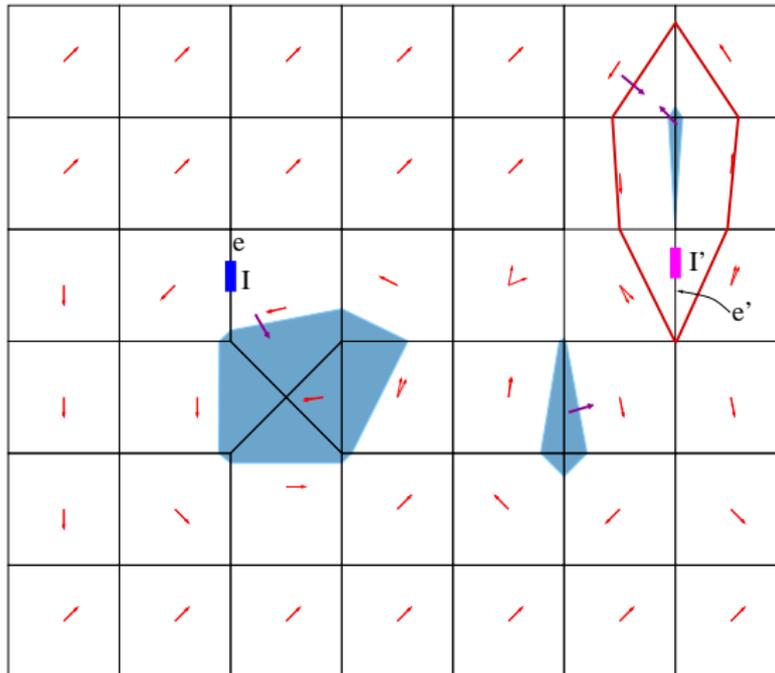

Theorem

Given an SPDI \mathcal{S} , a semi-separatrix γ , and edges e and e' , then, e' is reachable from e in \mathcal{S} if and only if e' is reachable from e in \mathcal{S} without the inert edges

State-Space Reduction using Kernels

Let e be a source edge and e' a target edge

- Identification of *redundant* edges
 - e_R is **redundant** if it lies on an opposite side of a controllability kernel as both e and e'

Theorem

Given an SPDI \mathcal{S} , a cycle σ , edges e and e' , then e' is reachable from e in \mathcal{S} if and only if e' is reachable from e in \mathcal{S} without the redundant edges

State-Space Reduction using Kernels

Let e be a source edge and e' a target edge

- Identification of *redundant* edges
 - e_R is **redundant** if it lies on an opposite side of a controllability kernel as both e and e'

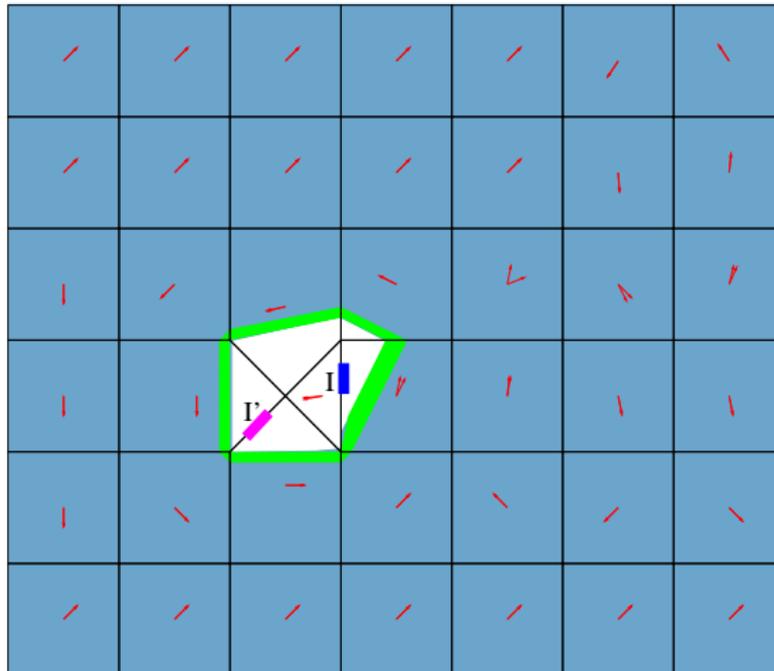

Theorem

Given an SPDI \mathcal{S} , a cycle σ , edges e and e' , then e' is reachable from e in \mathcal{S} if and only if e' is reachable from e in \mathcal{S} without the redundant edges

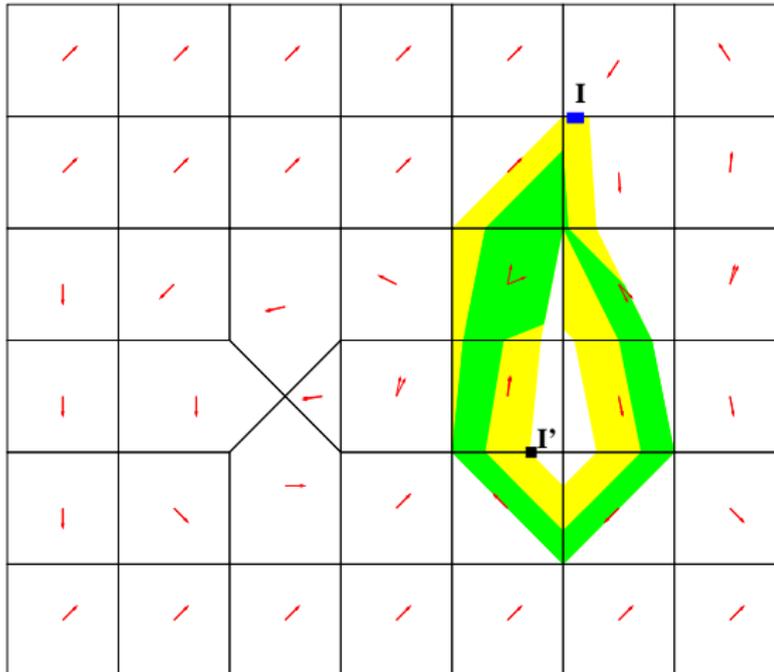

State-Space Reduction using Kernels

Example

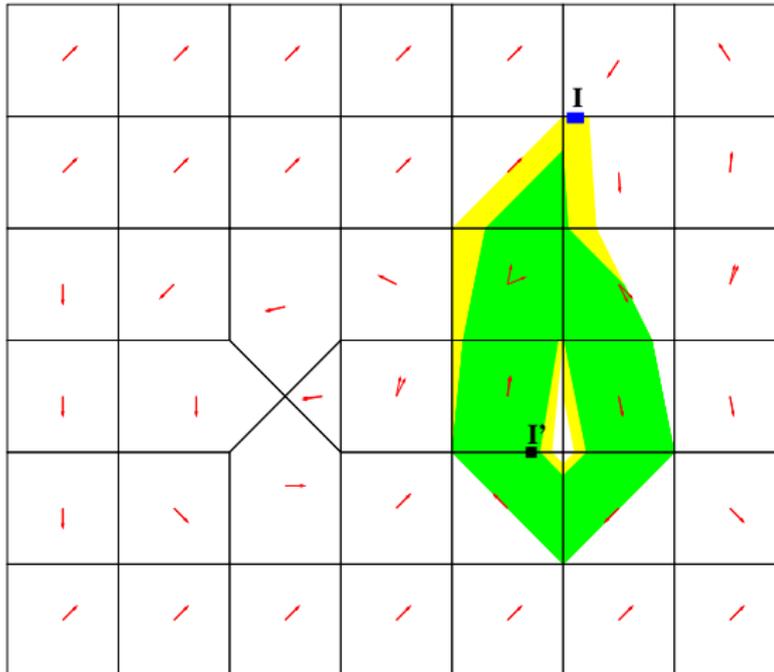

State-Space Reduction using Kernels

Immediate Answer

State-Space Reduction using Kernels

Immediate Answer

Final Remarks

Contributions

- Computation of Semi-Separatrices
- Use of the phase portrait objects to reduce the state-space (for reachability analysis)
 - No extra work needed to perform the optimization: identification and analysis of loops is performed in the first part of the reachability algorithm
- Combination of techniques
 - The detection of *inert* and *redundant* edges may be done by using standard geometrical test (odd-parity test, used in computer graphics)
 - The reduction is then performed on the graph

Final Remarks

Further Work

Extensions and Applications

- Not exact extensions to higher dimensions (undecidable)
 - Maybe use the idea for approximations
- Use of SPDIs for approximating non-linear differential equations on the plane
 - Approximation of phase portrait objects

Implementation

- Implementation in SPeeDI⁺
