

Web Applications 2017

Week 4, Slides 1

Content

- ES6 Overview
- Components
- Server vs client side components
- Web components
- Shadow DOM
- Custom elements
- Template tag
- Slots
- Babel, Polyfills and Webpack
- React components
- Java Server Faces

eqweq

ES6 (aka EcmaScript 2015)

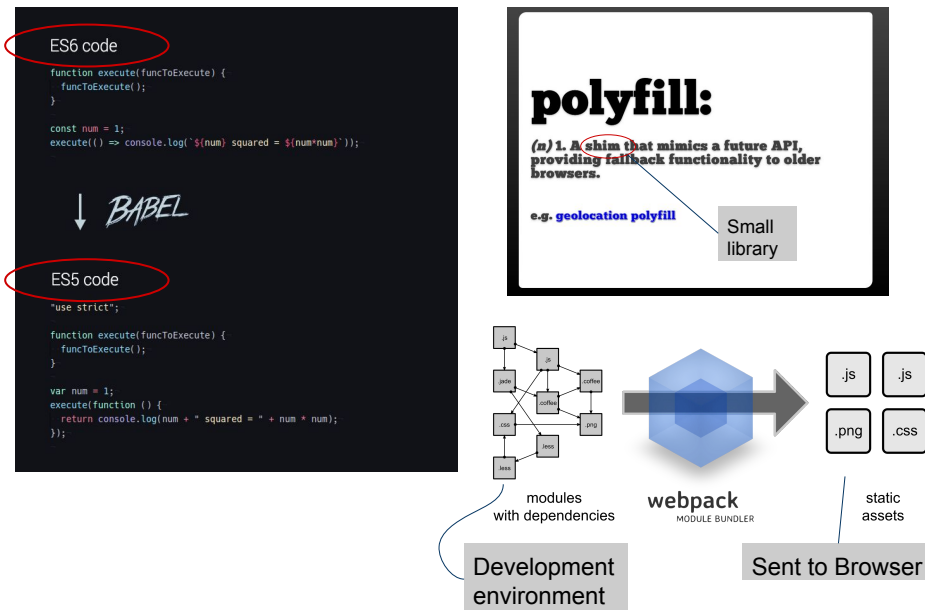

Of most interest right now ...

- [Modules](#)
- [Classes](#)
- [Template literals](#)
- [Arrow functions](#)
- [Block scope](#)

Readings

- [ES6 Overview features](#)

Babel, Polyfill and Webpack

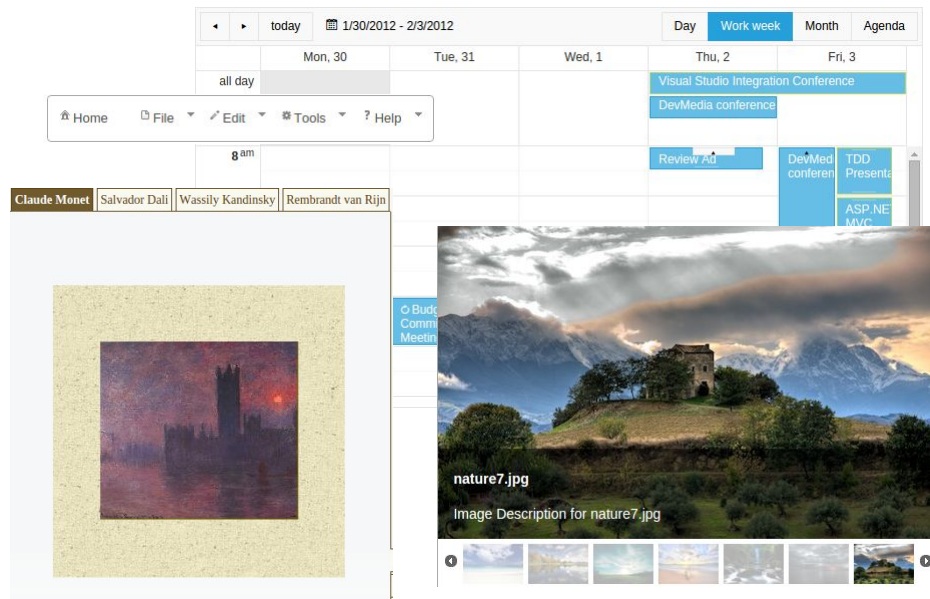

Tools needed.

- We need babel and webpack (because React uses them, upcoming).

Readings

- [Babel](#)
- [Polyfill](#)
- [Webpack](#)

Components: Basic Ideas

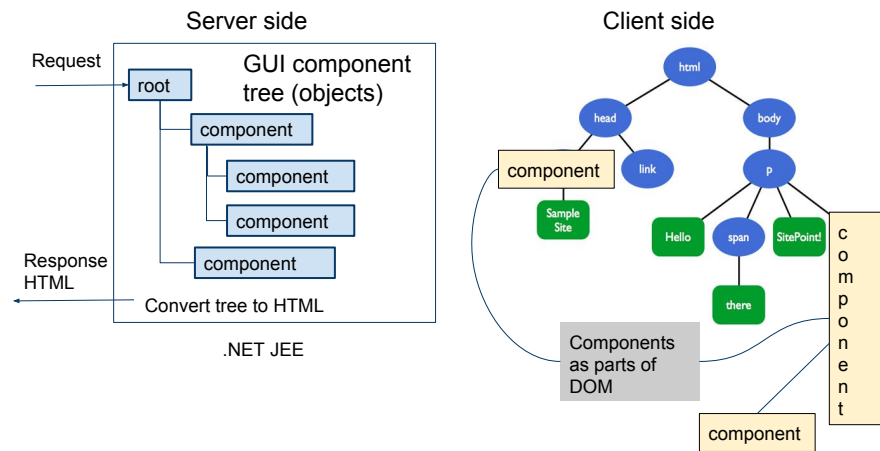

Basic idea is to do desktop programming on the web (like Swing, JavaFX)

- Skip all (own) CSS, JS, components hiding it all

Demo:

- [Mock OSX](#) (JEE, PrimeFaces)
- [Todo list](#) (React, client side components)

Server vs Client side Components

Server side: Let GUI live as a component tree (tree of objects) on server side

- One for each unique client, so tree must have unique id
- Translate to HTML (CSS, JS) and send to client for rendering

Client side

- Components attached to DOM
- Components (normally) created client side

Web Components

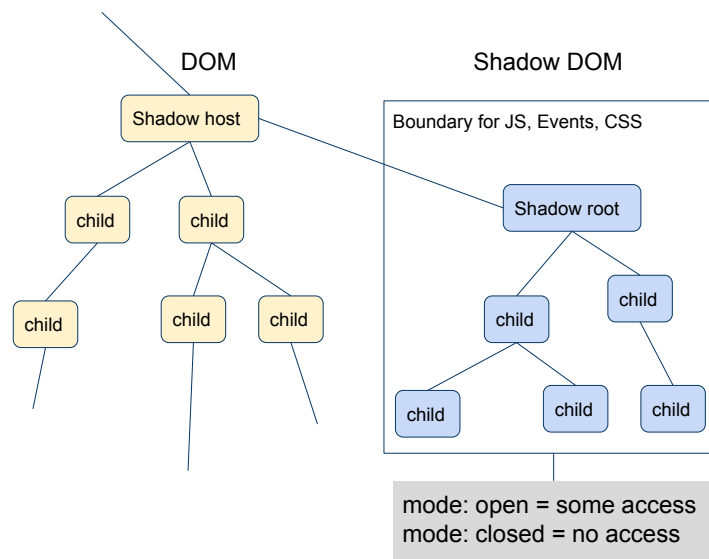

Specification from W3c (client side)

- [Shadow DOM](#)
- [Custom Elements](#)
- [HTML Templates](#)
- [HTML Imports](#) (cancelled?)

Readings

- [Current status W3C](#)
- [Web components MDB](#)

Shadow DOM

Readings

- [Shadow DOM](#) Google

Create a Shadow DOM

```
<!-- Not all elements can act as hosts -->
<p id="hostElement"></p>
<script>
  var host = document.querySelector('#hostElement');
  // create shadow DOM on the <p> element above
  var shadow = host.attachShadow({
    mode: 'open'
  });
  console.log(host);
  var shadowRoot = host.shadowRoot;
  console.log(shadowRoot);
  console.log(shadowRoot.host);

  shadow.innerHTML = '<p>Here is some new text</p>';

  var found = document.querySelector('#hostElement p');
  console.log(found); // NOT Found!
  var found = document.querySelector('p');
  console.log(found); // NOT Found!
  // Just affect p in shadow (not outer p's)
  shadow.innerHTML += '<style>p { color: red; }</style>';
</script>
```

Create shadow DOM

Shadow DOM encapsulated

Custom Element

A name

A [valid custom element name](#)

A local name

A local name

A constructor

A [custom element constructor](#)

A prototype

A JavaScript object

A list of observed attributes

A sequence<DOMString>

A collection of lifecycle callbacks

A map, whose four keys are the strings "connectedCallback", "disconnectedCallback", "adoptedCallback", and "attributeChangedCallback". The corresponding values are either a Web IDL Function callback function type value, or null. By default the value of each entry is null.

A construction stack

A list, initially empty, that is manipulated by the [upgrade an element](#) algorithm and the [HTML element constructors](#). Each entry in the list will be either an element or an *already constructed* marker.

Also custom
elements registry
references as JS
customElements

A Custom Element

```
class LoginElement extends HTMLElement {  
  constructor() {  
    super(); // Always first, establish prototype chain  
  }  
  
  connectedCallback() {  
    ...  
    this.attachShadow({mode: 'open'});  
    ...  
  }  
  
  render(){  
    this.shadowRoot.innerHTML = `<div id='content'>  
      <p>Please log in </p>  
      <table>  
        <tr><td> ...`  
  } // End class  
  // Register  
  customElements.define('log-in', LoginElement);  
  // In page  
<log-in></log-in>
```

Extend existing element

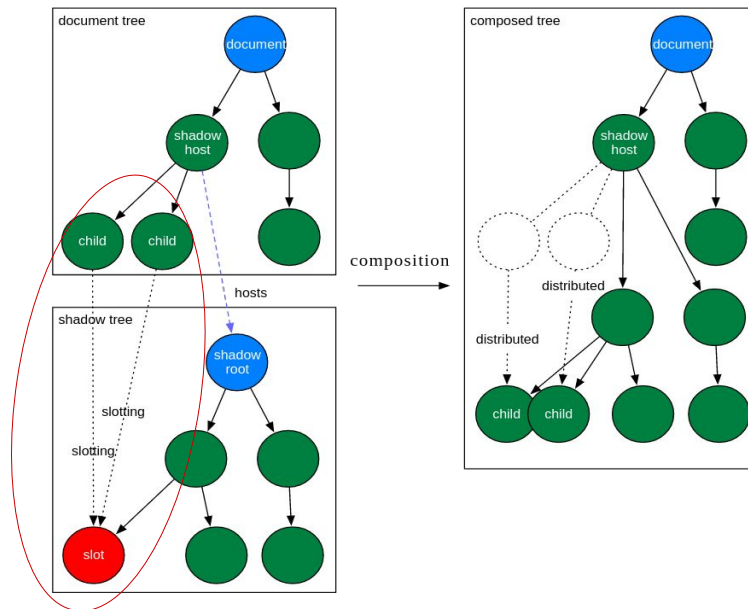

This is ES6

Register (must have "-" in name)

Template tag

```
<template id="login-template">
  <style>
    button {
      color: var(--button-text-color, pink); <!-- Problems -->
      font-family: var(--button-font);
      /*font-size: 24px;*/
    }
  </style>
  <div id='log-in'>
    <p>Please log in </p>
    <table>
      <tr>
        <td>Email</td>
        <td><input id='email' type='text' /></td>
      </tr>
      <tr>
        <td>Password</td>
        <td><input id='passwd' type='text' /></td>
      </tr>
      <tr><td><button id="btnLogin" type='button' />Login</td></tr>
    </table>
  </div>
</template>
```

Slots

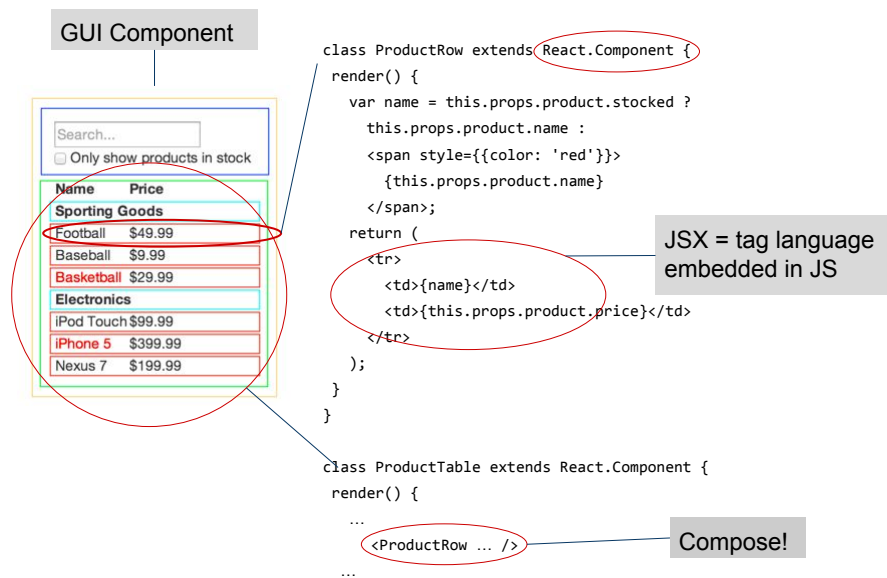

Slots

```
# shadowroot
<div id="tabs">
  <slot id="tabsSlot" name="title"></slot>
</div>
<div id="panels">
  <slot id="panelsSlot"></slot>
</div>

<!-- In page -->
<fancy-tabs>
  <button slot="title">Title</button>
  <button slot="title" selected>Title 2</button>
  <button slot="title">Title 3</button>
  <section>content panel 1</section>
  <section>content panel 2</section>
  <section>content panel 3</section>
</fancy-tabs>
```

React GUI Components

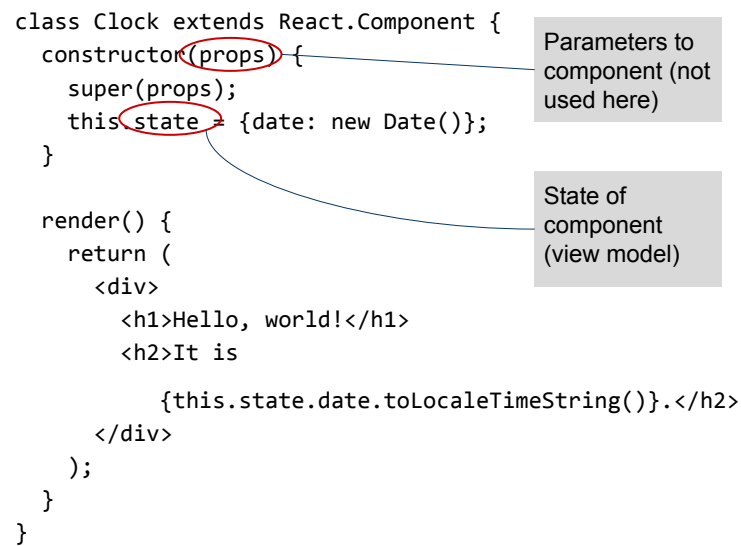

React is a GUI component framework (not full MVC framework)

Readings

- [React](#)

Props and State

```
class Clock extends React.Component {  
  constructor(props) {  
    super(props);  
    this.state = {date: new Date()};  
  }  
  
  render() {  
    return (  
      <div>  
        <h1>Hello, world!</h1>  
        <h2>It is  
          {this.state.date.toLocaleTimeString()}</h2>  
      </div>  
    );  
  }  
}
```

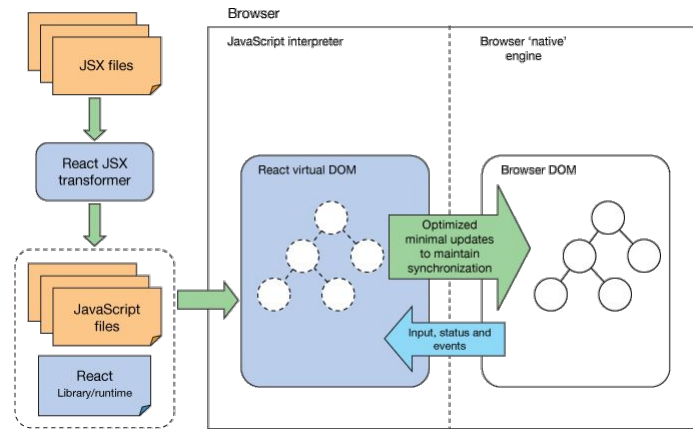

The diagram illustrates the concepts of props and state in a React component. It features a code snippet for a `Clock` class. Two red circles highlight `props` in the `constructor` and `state` in the `constructor`. A blue line connects the `props` circle to a grey box labeled "Parameters to component (not used here)". Another blue line connects the `state` circle to a grey box labeled "State of component (view model)".

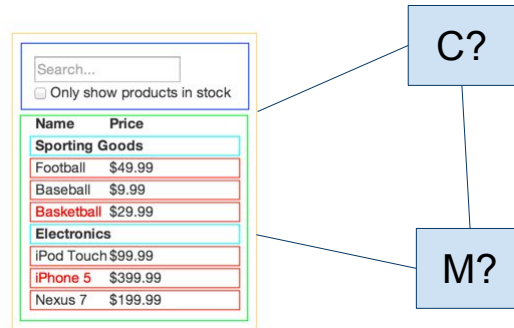

Parameters to component (not used here)

State of component (view model)

React Internals

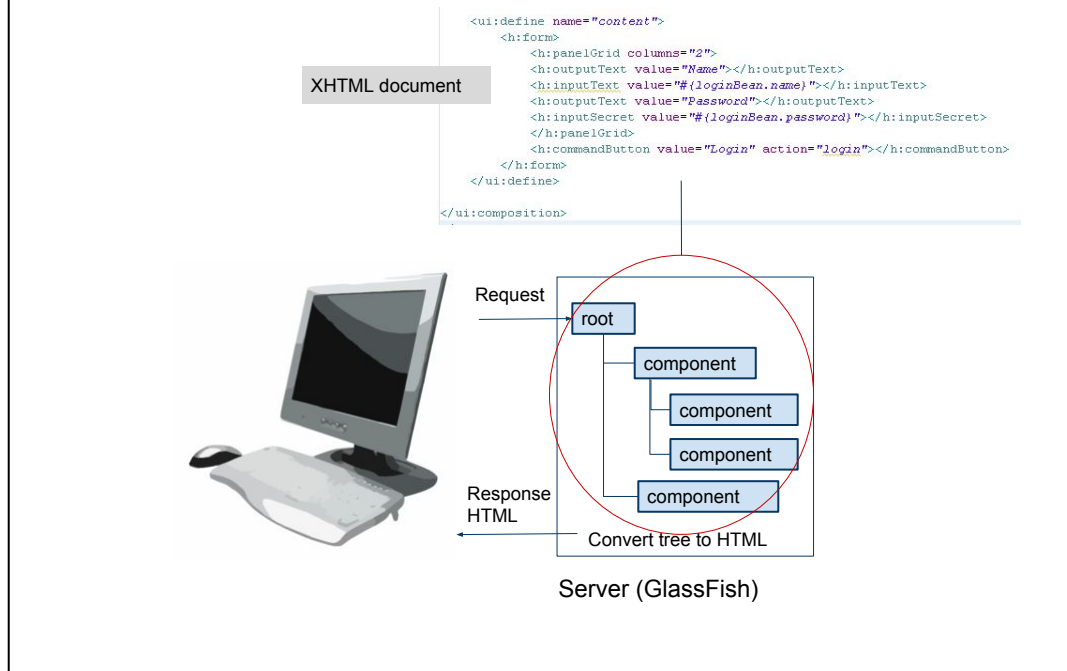

React MVC

Probably problems with Backbone (events)?

- [React and Backbone](#)
- [React and .NET](#)
- [Interesting critical article](#)

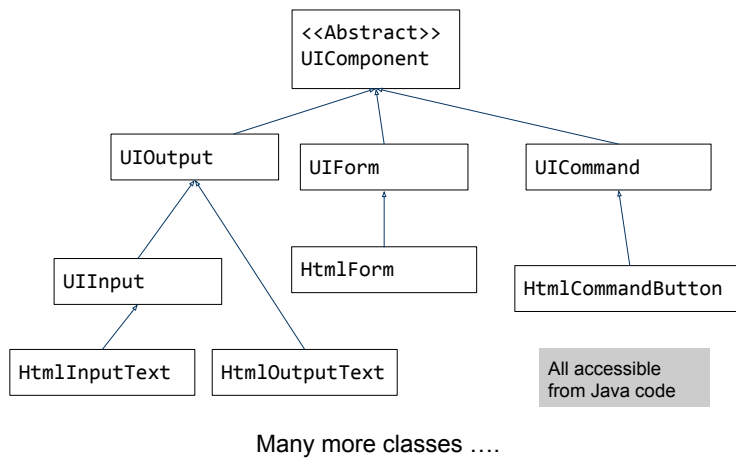

Java Server Faces

JSF is a server side (client) GUI technique

- Component tree "coded" as xhtml document (tedious to code in pure Java, ... but possible)
- NOTE: xhtml pages NOT returned!

JSF Component Classes

Server side component classes (tree of component objects),

- Toplevel is `UIComponent` (similar to Swing)
- Incoming data from HTTP-request will be converted and stored in the components
- Outgoing data retrieved from components
- A renderkit to translate components (and data) to renderable format (spec. requires a HTML renderkit).
 - Handled transparently by JSF
 - Example: `HtmlCommandButton` object → `<input type="submit" ... >` (String)

A JSF Page

Standard XHTML tags

```
<?xml version='1.0' encoding='UTF-8' ?>
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0
Transitional//EN"
"http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
<html xmlns="http://www.w3.org/1999/xhtml"
      xmlns:h="http://xmlns.jcp.org/jsf/html">
  <h:head>
    ...
  </h:head>
  <h:body>
    ...
  </h:body>
</html>
```

JSF tags, matching HTML

Readings

- [JSF HTML tag reference](#)
- [JSF implicit objects](#)

Post and Get

POST

```
<h:form>
    ...
    <h:commandButton ... />
    <h:commandLink action=.../>
</h:form>
```

GET

```
<h:link outcome=.../>
<h:button outcome=.../>
```

To send a POST request use

- `commandButton` or `commandLink`
- Must be inside `<h:form...>`
 - And so must the input controls too (`<h:inputText...>`, etc.)
- NOTE: `<h:form>` has no `action` attribute. Will "post back" to same page

To send a GET use

- `link` or `button`
- No need for `<h:form ...>`

Important, POST and GET will control behaviour of JSF, see JSF Request Cycle, later

...

Expression Language in JSF

EL as read

```
<h:outputText value="#{person.name}"/>
```

EL as write

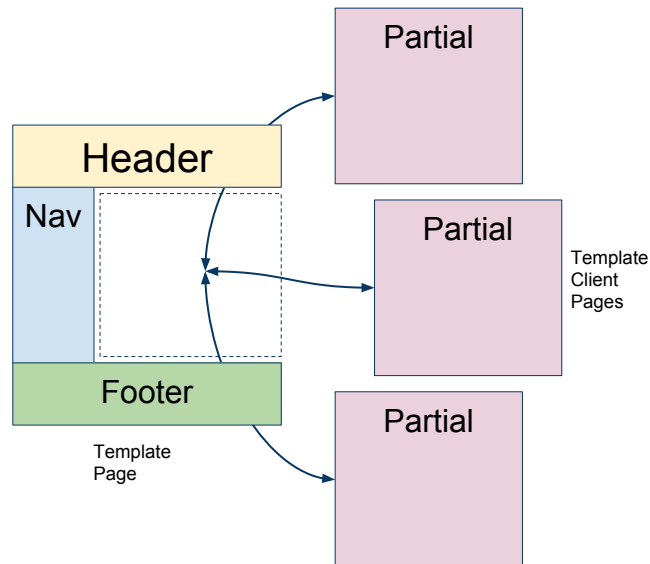

```
<h:inputText value="#{person.name}"/>
```

A CDI bean (Java object handled by Context and dependency injection)

Same idea as JSP. Used as in JSPs but

- ... uses deferred syntax
- **#**{ ... expression ... }
 - Deferred is both read and write (depends on expression location)
 - Input vs output component
- JSP used immediate syntax **\$**{...expression...}
 - Immediate syntax is read only

JSF Templating: Facelets

[Facelets](#) refers to the templating technique (view declaration language) for JavaServer Faces technology

Readings

- [Facelets tag reference](#)

Template and Client

```
<h:outputStylesheet library="css"
                    name="default.css" />

<div id="left">
  <ui:insert name="left"/>
</div>
<div id="content" class="content">
  <ui:insert name="content" />
</div>
```

template.xhtml

```
<ui:composition template="template.xhtml">

  <ui:define name="left">
    <!--Any left content here -->
  </ui:define>

  <ui:define name="content">
    <!-- Any content here -->
  </ui:define>
</ui:composition>
```

User never access template file (page) directly

- Request URL is the client file (page)

Master Detail Interface

```
<h:link value="Edit" outcome="personDetail">
  <f:param name="id" value="#{person.id}" />
  <f:param name="fname" value="#{person.fname}" />
  <f:param name="age" value="#{person.age}" />
</h:link>
```

Get data from bean

Masterpage

```
<f:metadata>
  <f:viewParam name="id" value="#{personDetail.id}" />
  <f:viewParam name="fname" value="#{personDetail.fname}" />
  <f:viewParam name="age" value="#{personDetail.age}" />
</f:metadata>
```

Put data into bean

Detailpage

HTML and JSF

Pass through elements

```
<input type="email" placeholder="Enter email"
      jsf:value="#{htmlbean.email}" required="required"/>

<label jsf:value="#{htmlbean.email}" />
```

Pass through attributes

```
<h:inputText id="email" value="#{htmlbean.email}"
             p:type="email" p:placeholder="Enter email"/>
```

Possible to let JSF and HTML work in conjunction (HTML5 friendly JSF)

Pass-through elements

- In HTML5 (i.e. no JSF-elements) use JSF attributes (and EL expressions)
- Make it possible to build the view with HTML elements that can access components and beans
 - Will convert HTML to JSF
 - Mapping between HTML-elements and JSF in [TagDecorator](#)
- To make an element a pass-through element, at least one of its attributes must be in the namespace `http://xmlns.jcp.org/jsf`.

Pass-through attributes

- In JSF (using JSF-elements), use HTML5 attributes
- Attributes passed through JSF directly to render phase
- Prefix attributes with namespace `http://xmlns.jcp.org/jsf/passthrough`

AJAX Behaviour

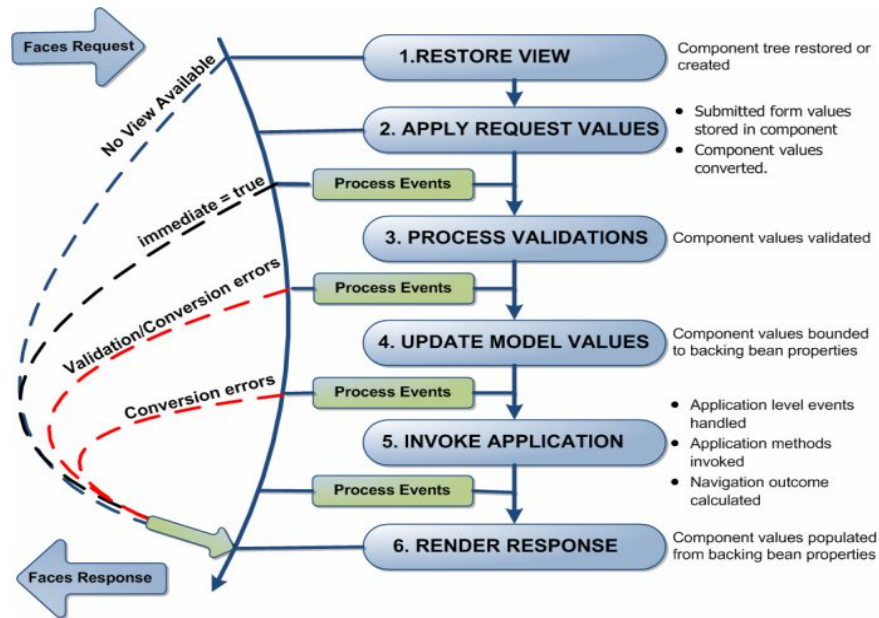

The AJAX element

```
<h:form>
  <h:inputText value="#{ajaxbean.bound}" />
  <h:commandButton ... >
    <f:ajax render="output" execute="@form" />
  </h:commandButton>
  <h:outputText id="output" value="#{ajaxbean.randnumb}" />
</h:form>
```

JSF is default "full page load"

- Need for AJAX ...?? If so ... [<f:ajax>-element](#)
- There are 4 special values for attributes execute and render
 - @this. The element enclosing f:ajax.
 - @form. The h:form enclosing f:ajax.
 - Very convenient if you have multiple fields to send
 - @none. Nothing sent.
 - Useful if the element you render changes values each time you evaluate it.
 - @all. All JSF UI elements on page.

JSF Request Cycle

To emulate desktop programming (but having a network in between) things must be done in an orderly fashion

Readings

- [JSF request cycle](#)
- more about the [same](#).

Higher Level Libraries

Readings

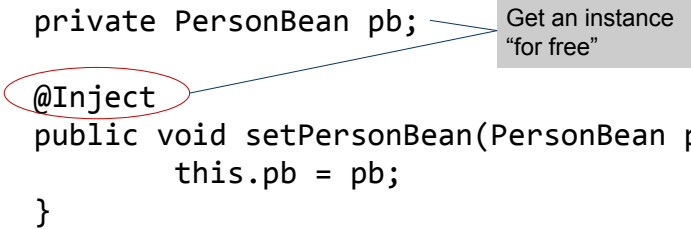

- [PrimeFaces](#)
- [ICEFaces](#)
- [OpenFaces](#)

Context and Dependency Injection

```
import javax.inject.Inject;

private PersonBean pb;

@Inject
public void setPersonBean(PersonBean pb) {
    this.pb = pb;
}
```

A blue line originates from the `@Inject` annotation and points to the `pb` variable in the `private PersonBean pb;` line. A grey box containing the text "Get an instance 'for free'" is connected to the end of this line.

Readings

- [Contexts and Dependency Injection](#) (CDI)
- [Weld](#) reference implementation

CDI Bean

```
import javax.enterprise.context.RequestScoped;

@Named("personbean")
@RequestScoped
public class PersonBean implements
    Serializable {

    private int age;

    public int getAge(){ ... }
    public void setAge(int age){ ... }
}
```

CDI Beans as Listeners

Call methods on
CDI beans

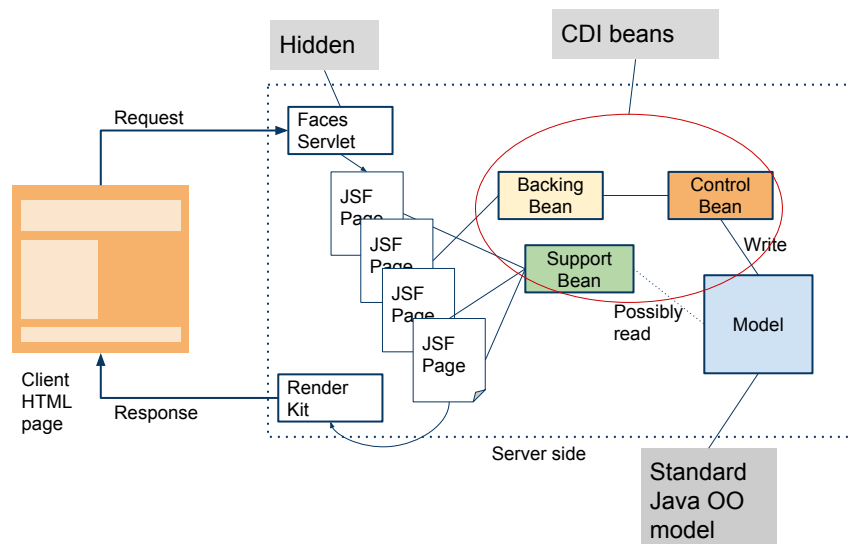

```
<h:commandButton ...  
    actionListener="#{bean.doActionListener}".../>
```

```
<h:commandButton ...  
    action="#{bean.anyMethod}" />
```

Must return String, used for navigation

```
<h:inputText ... valueChangeListener="#{bean.doValueChange}" />
```

JSF MVC

JEE MVC Java Server Faces for GUI

- Backing bean (Viewmodel): Holder for data. 1:1 with some page, request scoped
- Control bean: In control layer, transfer data from/to model. Act as listener (action attribute in element) , request scoped
- Support bean: Supply data common to more pages, session or application scoped

Readings

- [CDI bean roles](#)
