Model-Based Testing (DIT848 / DAT261) Spring 2017

Lecture 1 Overview of Verification and Validation

Gerardo Schneider gerardo@cse.gu.se Dept. of Computer Science and Engineering Chalmers | University of Gothenburg

Some slides based on material by Magnus Björk, Thomas Arts and Ian Somerville

Lecture 1

 Introduce software verification and validation and discuss the distinction between them

Introduce link between development and test

Lots of new words, putting them into context

Discuss: What is SW quality?

* Downloaded from youtube

Launch of Windows Vista (2006)

Quality aspects considered in this course

High priority

- Correctness:
 - The program should fulfill its specification
 - The program should not malfunction (crash, undesired side effects...)

Lower priority

- Suitability
- Usefulness

Code maintainability / standards conformance

Document quality

Motivation

Product development costs

How much do you think testing "costs"?

Motivation

Product development costs (Sommerville)

The more mature innovations get, the more important their quality

Example: GPS receiver (high expectations on accuracy)

"Software quality" is getting a competitive distinction

The company being able to test better for less money gets the market

Bugs are serious

Ariane 5 flight 501 (1996)

- Error in a code converting 64bit floating-point numbers into 16-bit signed integer: It triggered an overflow condition
- Rocket disintegrates 40 seconds after launch
- Price: ~USD 370M in equipment
- Therac-25 Radiation therapy machine
 - Possible to configure the Therac-25 so the electron beam would fire in high-power mode but with the metal X-ray target out of position
 - Source of error: a "race condition"
 - Price: 5 people killed by massive overdoses

More recent bugs: http://www.tricentis.com/blog/2015/05/05/software-failures-of-2015-quarter-one/

Verification & Validation

Verification

"Are we building the product right"

The software should conform to its specification

Validation

"Are we building the right product"

The software should do what the user really requires

V model [cf Spillner 2000]

How does it work in practice?

• This is what we will see in this course...

- Remember that the V-model is useful to show how development and test are related conceptually
 - Not as a guideline on how software should be developed
 - In practice, different ways to organize/perform testing
- We will see "traditional" ways of performing testing
- And obviously Model-Based Testing (MBT)

Dynamic and static verification

DYNAMIC

- *Software testing* & runtime verification
 - Concerned with exercising and observing behaviour
 - The system is executed (with test data or in a real environment) and its operational behaviour is observed

STATIC

- Software inspections & other model-based techniques (static analysis/ verification, model checking, etc)
 - Concerned with analysis of the system before execution (source code or model)
 - May be supplemented by tool-based document and analysis

Error, defect, failure...

• Error

A human action that produces an incorrect result

- Mistakes in syntax, wrong invocation, wrong initialization of variables, ...
- Defect (or bug, or fault)

A flaw in a component/software that might cause the system to fail to perform its required function If encountered during execution: might cause a *failure*

Incorrect statement or data definition

• Failure

Deviation of the component/software from its expected result

• The program crashes, the wrong result is obtained

According to the "International Software Testing Qualification Board" (ISTQB) Warning: Not everybody agrees with the above distinction!

V&V process

- It's a whole life-cycle process
 - V&V must be applied at each stage in the software process
 - So, V&V and development processes depend on each other

- Has two principal objectives
 - The discovery of defects in a system
 - The assessment of whether or not the system is useful and useable in an operational situation

V&V process

Goals

 Verification and validation should increase confidence on that the software fits the intended purpose

• This does **NOT** mean completely free of defects

 Rather, it must be good enough for its intended use and the type of use will determine the degree of confidence that is needed

V&V process

Confidence on Sw correctness depends on

- Software function
 - How critical the software is to an organization
- User expectations
 - Users may have low expectations of certain kinds of software

Marketing environment

 Getting a product to market early may be more important than finding defects in the program

Patchability

Can sold units be upgraded easily?

Discussion Software Testing in Automobiles

Discuss software in the car

Discuss for several software components:

- How critical they are
- What the users expect
- How the marketing environment looks like

Offset crash test at 64km/h

Whether upgrades are feasible

V&V planning

- Careful planning is required to get the most out of static and dynamic verification
- Planning should start early in the development process
- The plan should identify the balance between *dynamic* and *static* techniques (e.g., between testing and inspection)
- V&V planning is about defining standards for the V&V process, rather than describing product tests

 The more critical the system, the more effort should be devoted to static analysis/verification

V&V planning

Plan V&V process

- Which activities?
- Which results for each activity?
- Who performs activity?

V-model helps connecting test activities to development activities

Each development activity corresponds to a test level

Test levels

Test level: A group of test activities that are organized and managed together

A test level is linked to responsibilities in a project

For each level, it is important to test what was not possible to verify or validate on lower levels

Different methods and techniques may apply to each level

Verification and Validation

Verification and Validation

Dynamic verification

- Testing can reveal the presence of errors NOT their absence (Dijkstra 1960's)
- The "only" validation technique for non-functional requirements as the software has to be executed to see how it behaves
 - Non-exhaustive
- Should be used in conjunction with static verification to approximate a full V&V coverage

Types of testing (one possible classification)

Defect testing

- Tests designed to discover system defects
- A successful defect test is one which reveals the presence of defects in a system

Validation testing

- Quality assurance process carried out before the software is ready for release
- To show that the software meets the requirements given by the user
 - Acceptance by the end user
- A successful test is one that shows that requirements have been properly implemented

Testing and debugging

• Defect testing and debugging are distinct processes

- Testing is concerned with establishing the existence of defects in a program
- **Debugging** is concerned with locating and repairing these errors
 - Debugging involves formulating a hypothesis about program behaviour then testing these hypotheses to find the errors

Cost of debugging is often included in costs for software testing

Software inspections

Software inspection is a manual static analysis method

- It involves people/tools examining the source representation with the aim of discovering anomalies and defects
- Inspections can take place on all development levels, no matter the formality of the sources
- Inspections do not require execution of a system so may be used before implementation
- They may be applied to any representation of the system (requirements, design, configuration data, test data, etc.)
- Shown to be an effective technique for discovering program errors

Inspection success

- Many different defects may be discovered in a single inspection
 - In testing, one defect may mask another so several executions are required
- They reuse domain and programming knowledge so reviewers are likely to have seen the types of error that commonly arise
- Incomplete versions of a system can be inspected without extra cost
- You can look for inefficiencies, poor programming style, etc

Inspections and testing

- Inspections and testing are complementary and not opposing verification techniques
- Both should be used during the V&V process
- Inspections can check (partial) conformance with a specification but not conformance with the customer's real requirements
- Inspections cannot check non-functional characteristics such as performance, usability, etc.
 - But inspections can find other non-functional characteristics such as standards compliance of code

Verification and Formal Methods

 Formal methods can be used when a mathematical specification of the system is known

- They are the *ultimate* verification technique
 - Why not use FM instead of testing?

Usually requires highly specialized engineers! (to model and interpret results)

 They involve detailed mathematical analysis of the specification and may develop formal arguments that a program conforms to its mathematical specification

Typical testing methods on each level

• Unit tests:

- Each programmer required to write unit tests for own code, organized in automatically executable test suites
- Automatic static analysis/verification (lint/splint-like)
- Manual code inspections

Integration tests:

- Write test cases that monitor how modules interact
- Some manual code inspections

• System tests:

- Scripted test suite
- Manual tests trying to break the system

Acceptance tests:

Customer manually tests software

Model-Based testing (automatic test extraction from a model) not specifically associated with a level -> Needs a model!

Conclusions

- Verification and validation are not the same thing
 - Verification shows conformance with specification;
 - Validation shows that the program meets the customer's needs
- V&V plans should be drawn up to guide the V&V process (part of the V&V plan is a test plan)
- Each design activity has a corresponding V&V activity
- Static verification techniques involve examination and analysis for error detection (among others)

Dynamic verification implies "running" the code

Terminology
