

TDA362/DIT224 – Computer Graphics

Teacher: Ulf Assarsson
Chalmers University of Technology

This Course

- Algorithms!

Understanding Ray Tracing

Real-time Rendering

Course Info

- Study Period 2 (lp2)
- Real Time Rendering, 4th edition
 - Available on Cremona at discount.
- [Schedule](#):
 - Mon 13-15, w2 only
 - Tues 10-12,
 - Fri 9-12,
 - ~14 lectures in total, ~2 / week
 - Lab slots:
 - Mon: 17-21
 - Tues: 13-21
 - Wed: 13-21
 - Thur: 9-12 + 17-21
- [Homepage](#):
 - Google “TDA362” or
 - “Computer Graphics Chalmers”

Tutorials

- All laborations are in C++ and OpenGL
 - Industry standard
 - No previous (C++) knowledge required
- Six shorter tutorials that go through basic concepts
 - Basics, Textures, Camera&Animation, Shading, Render-to-texture, Shadow Mapping
- One slightly longer lab where you put everything together
 - Real-time rendering
 - or
 - Path tracer

Tutorials 1-6

Don't just
copy/paste 😊

Rendering a
triangle

Textures

Particle System

Height field

Custom environment map (difficult)

Path Tracing

Tutorials

- Info: <http://www.cse.chalmers.se/edu/course/TDA362/tutorials.html>
- To pass the tutorials:
 - Present your solutions to lab assistant.
 - Deadlines:
 - Lab 1+2+3: Thursday week 2.
 - Lab 4 : Thursday week 3.
 - Lab 5+6: Thursday week 4
 - Lab 7 / Project: Thursday week 7.
- Do the tutorials in groups (Labgrupper) of two, or individually if you prefer.
- First deadline: Thurs. next week.

Computer Graphics:

– two main principles...

...for computer-generating the appearance of a virtual 3D scene:

- Ray Tracing:

- **Forward** ray tracing: Tracing light beams from light sources and how they reach the virtual camera.
- **Backward** ray tracing: Tracing the light beams backwards, i.e., from the camera and all the way back to the light sources.

- Rasterization:

- Draw the scene triangles one by one onto the pixels of the screen and, for each pixel, compute the color (by regarding light sources and perhaps also surrounding objects).

Forward Ray Tracing

One way to form an image is to follow rays of light (or photons) from a point source finding which rays enter the lens of the camera. Each ray of light may have multiple interactions with objects before being absorbed or going to infinity.

Pros: Algorithmically very easy to generate physically correct images.

Cons: Extremely slow. Only few of the traced rays will hit the camera sensor and actually contribute to the image.

“Trace some trillion photons and you probably have a good image.”

Backward Ray Tracing

- Follow rays of light backwards, i.e., from the camera sensor (center of projection) into the scene until they either are absorbed by objects or go off to infinity.

- At each bounce position, estimate incoming light intensity and color by following possible bounce directions, given the material.

- Cons: Complicated but possible to get accurate convergence. We use Monte-Carlo sampling theory from maths for how to best sample an unknown signal. E.g., we do not know photon density nor from which direction the photon came. Combinations of forward + backwards ray tracing can be used to remedy this.

- Pros: Faster but still slow compared to rasterization

“Trace a billion rays backwards and you probably have a great image.”

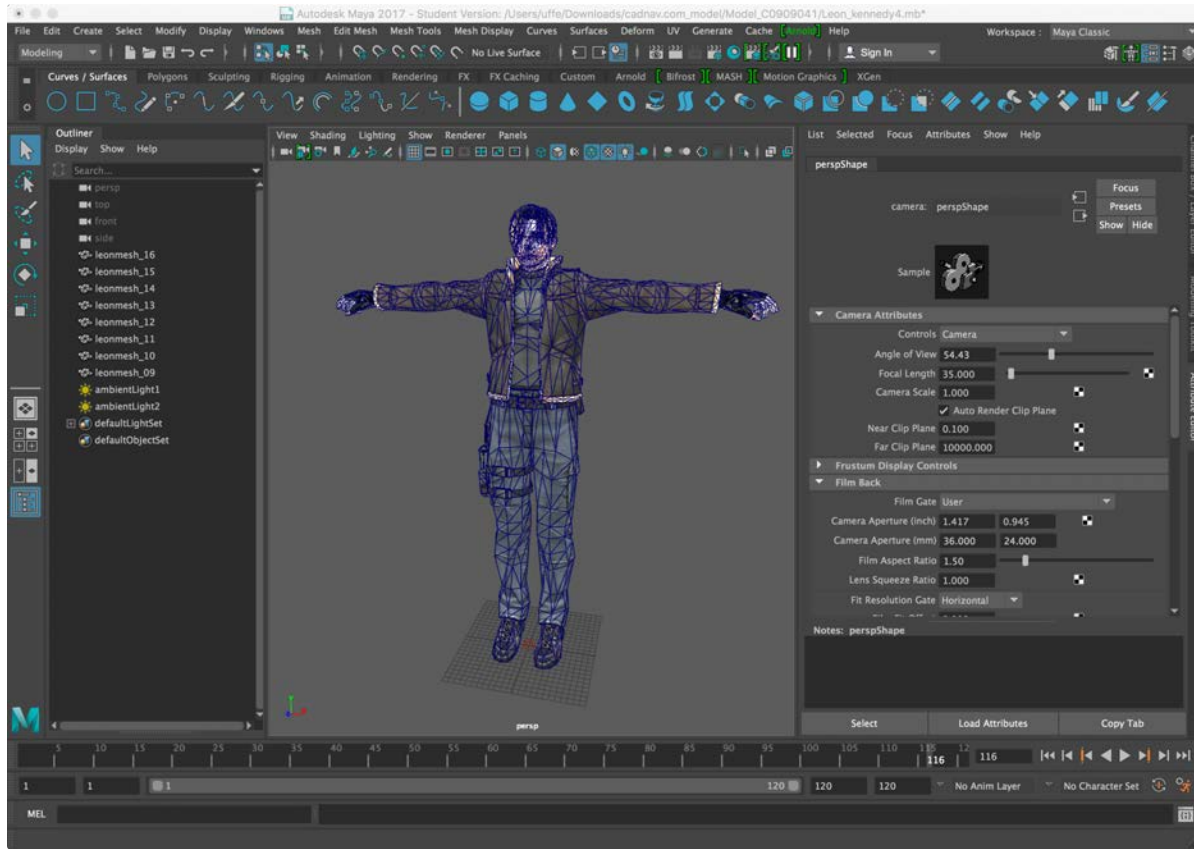

Real-Time Rendering

based on Rasterization

Overview of the
Graphics Rendering Pipeline
and OpenGL

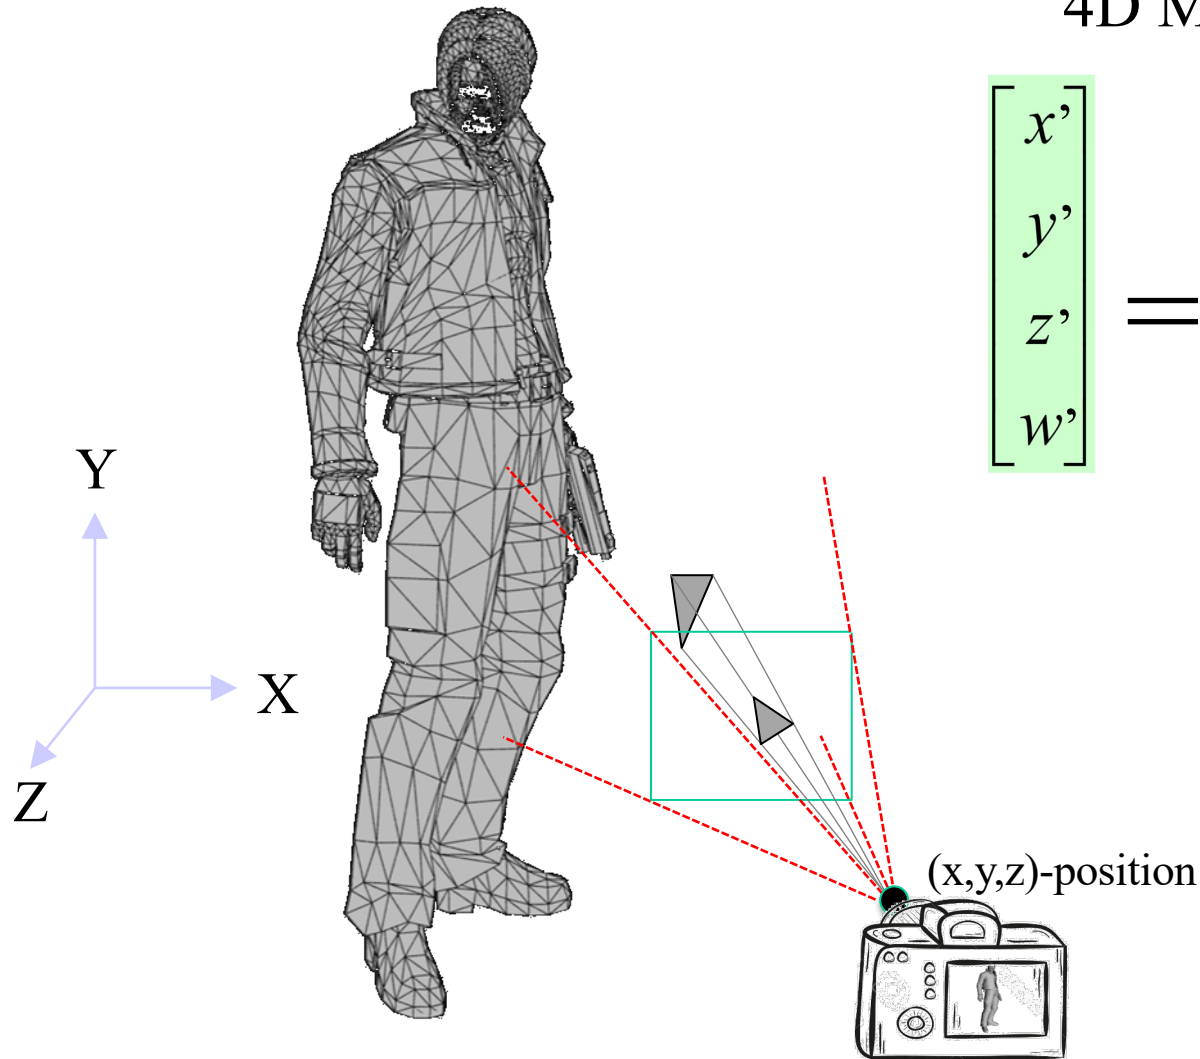

3D-models: surfaces are constructed by triangles.

4926 triangles

Why triangles?

Each triangle is projected onto the image plane using a virtual camera.

4D Matrix Multiplication

$$\begin{bmatrix} x' \\ y' \\ z' \\ w' \end{bmatrix} = \begin{bmatrix} s_x & \bullet & \bullet & t_x \\ \bullet & s_y & \bullet & t_y \\ \bullet & \bullet & s_z & t_z \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \\ w \end{bmatrix}$$

The graphics card draws the triangles onto the screen.

How compute pixel color?

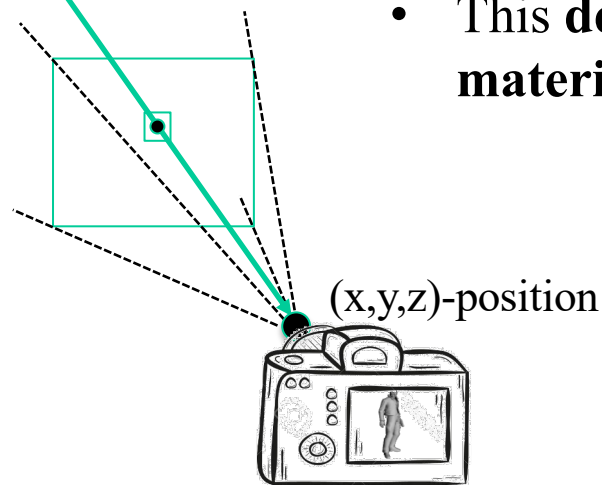

Use some *shading* model based on light sources and triangle's material:

 (x,y,z) Light source

At rendering (for each frame):

- The graphics card computes, the reflected light toward the camera.
 - per pixel (or per vertex and using interpolation per pixel),
- This **depends on the light and material parameters.**

Triangle colors:

are typically multiplied with the lighting contribution. Instead of one single color per triangle, you can use a *texture* (=image) – to simulate details and materials.

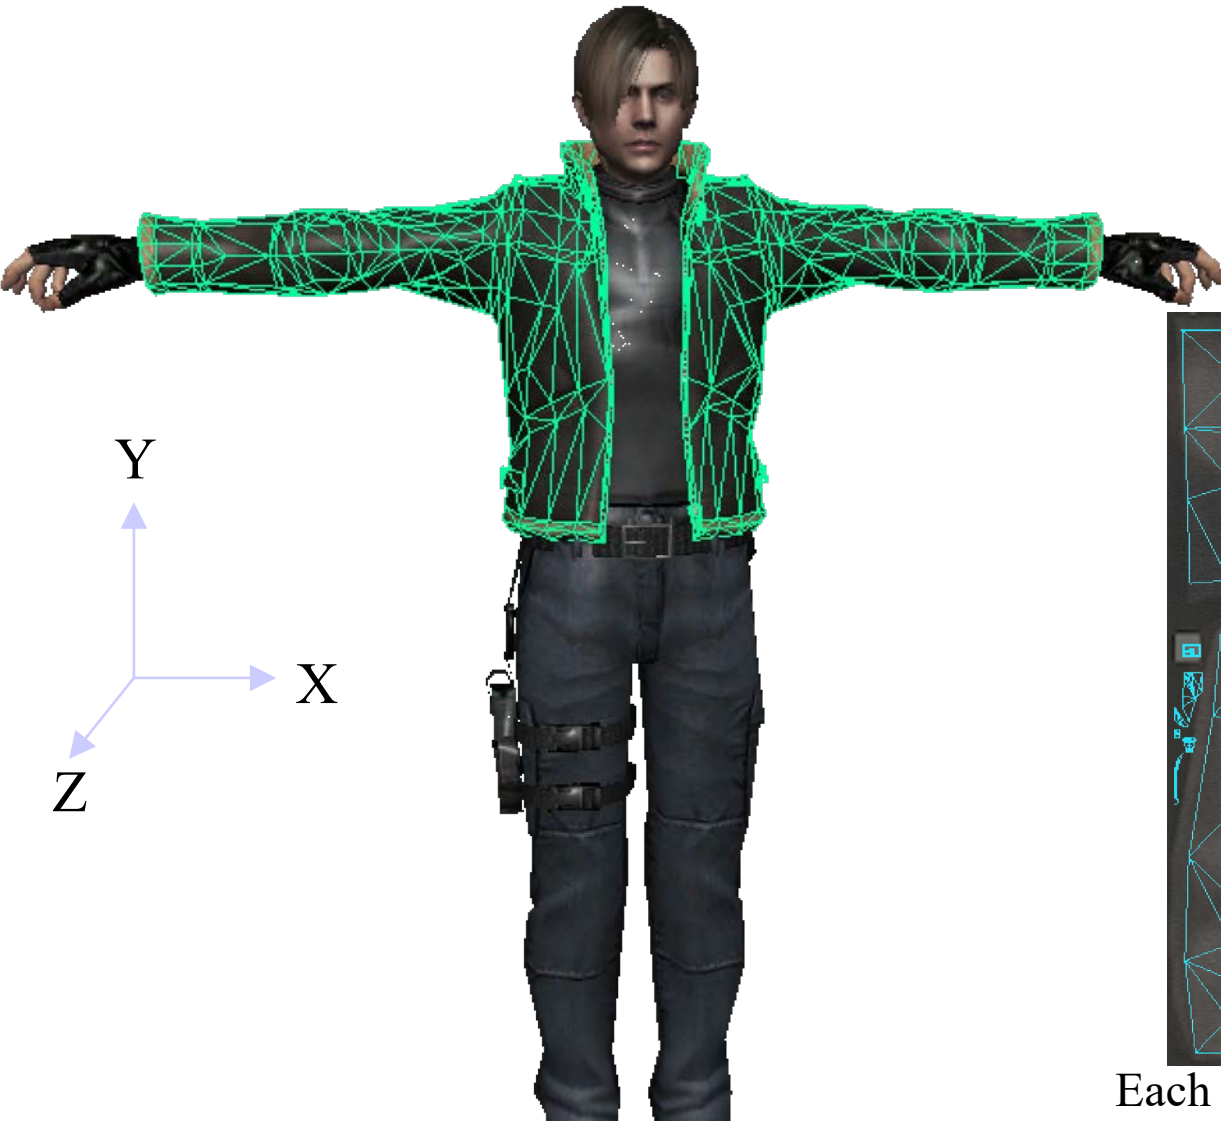

- The **texture** color is modulated (often just multiplied) with the light intensity to get the final pixel color.

Specify which part of the texture that each triangle covers.

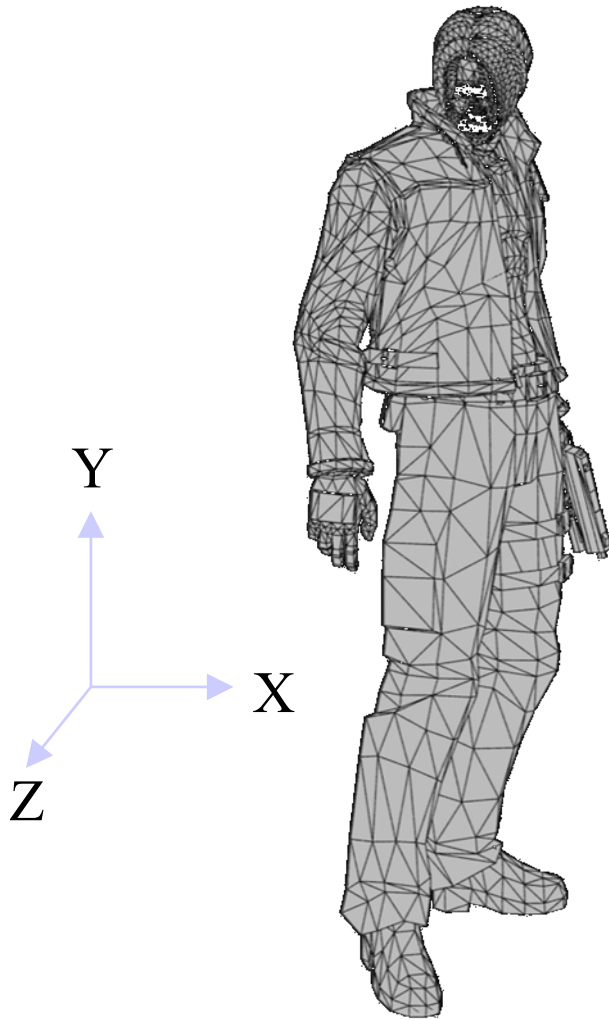

Texture Maps

Each triangle's mapping to texture space

Summary of this very simple type of shading model:

There are many others. Details are given in Lecture 3+4.

triangles

lighting

+ texturing

The Graphics Rendering Pipeline

The Application stage, geometry stage, and rasterizer stage

You say that you render a ”3D scene”, but what is it?

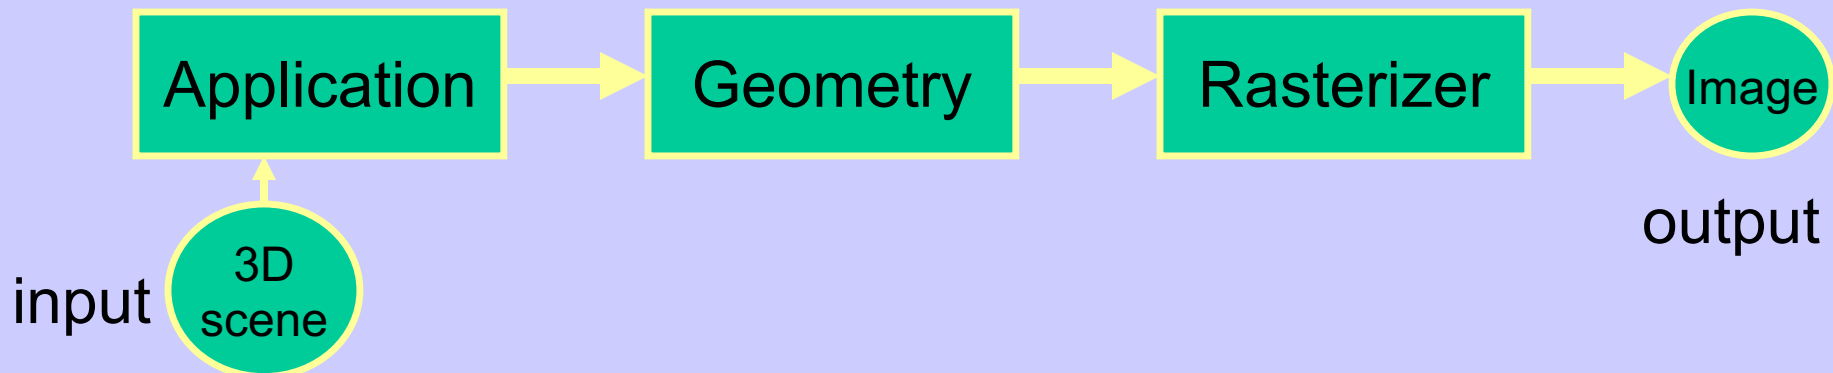

- First, of all to take a picture, it takes a camera – a virtual one.
 - Decides what should end up in the final image
- A 3D scene is:
 - Geometry (triangles, lines, points, and more)
 - Light sources
 - Material properties of geometry
 - Colors, shader code ,
 - Textures (images to glue onto the geometry)
- A triangle consists of 3 vertices
 - A vertex is 3D position, and may have an attached normal, color, texture coordinate,

Lecture 1: Real-time Rendering

The Graphics Rendering Pipeline

- The pipeline is the "engine" that creates images from 3D scenes
- Three conceptual stages of the pipeline:
 - Application (executed on the CPU)
 - Geometry
 - Rasterizer

The APPLICATION stage

- Executed on the CPU
 - Means that the programmer decides what happens here
- Examples:
 - Collision detection
 - Speed-up techniques
 - Animation
- Most important task: feed geometry stage with the primitives (e.g. triangles) to render

The GEOMETRY stage

- Task: "geometrical" operations on the input data (e.g. triangles)
- Allows:
 - Move objects (matrix multiplication)
 - Move the camera (matrix multiplication)
 - Lighting computations per triangle vertex
 - Project onto screen (3D to 2D)
 - Clipping (avoid triangles outside screen)
 - Map to window

Application

Geometry

Rasterizer

The GEOMETRY stage

Vertex
Shading

Projection

Clipping

Screen
Mapping

- Vertex Shader
 - A program executed per triangle vertex, computing:
 - Transformations
 - Projection (3D->2D)
 - Compute a color per vertex
- Clipping
- Screen Mapping

The RASTERIZER stage

- Main task: take output from GEOMETRY and turn into visible pixels on screen

- Computes color per pixel, using fragment shader (=pixel shader)
 - textures, (light sources, normal), colors and various other per-pixel operations
- And visibility is resolved here using the fragment's z-value to check its visibility

The rasterizer stage

Triangle Setup:

- collect three vertices + interpolated vertex shader output (incl. normals) and make one triangle.

Triangle Traversal

- Scan conversion or rasterization

Pixel Shading

- Compute pixel color

Merging:

- output color to screen

The three stages' correlation to hardware

The Application stage, geometry stage, and rasterizer stage

Graphics Pipelines

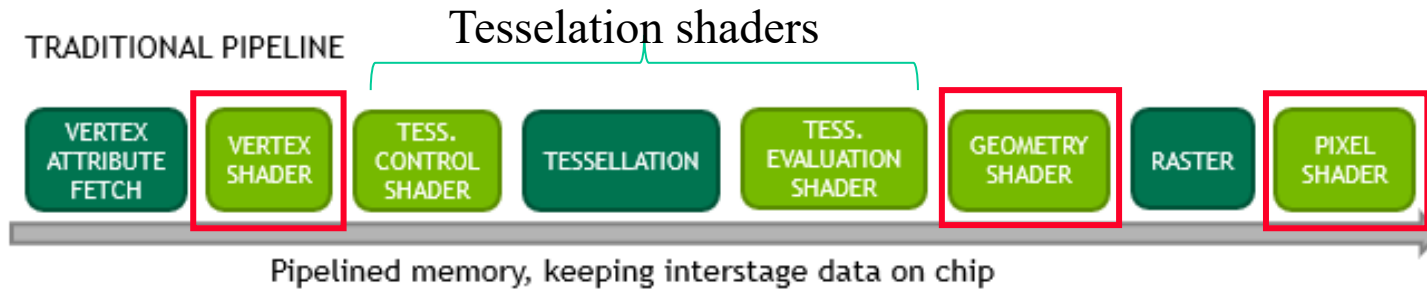

Compatibility:

- OpenGL 4.3
 - WebGL 2
 - OpenGL ES 3
- i.e., phones, web, PCs...

We focus on:

Full traditional pipeline:

Mesh shaders (still very new):

TASK/MESH PIPELINE

Compatibility:

- OpenGL 4.5 extension
- DirectX 12 Ultimate
- Vulkan

What are vertex and fragment (pixel) shaders?

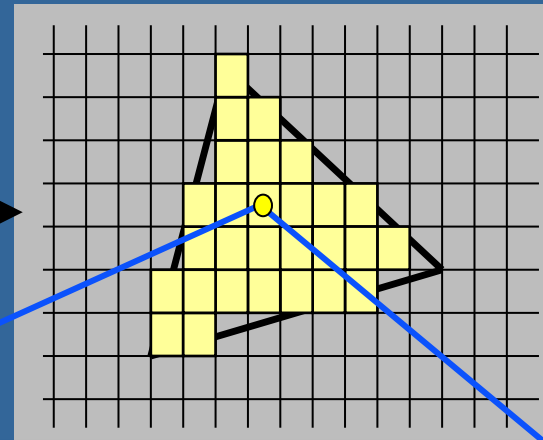

- Vertex shader: reads from textures. Writes outputs per vertex, which are interpolated and input to the fragment shader invocation per pixel.
- Fragment shader: reads from textures, writes to pixel color.
- Memory: Texture memory (read + write) typically 4 GB – 16 GB
- Program size: the smaller the faster

● For each vertex, a vertex program (vertex shader) is executed

● For each fragment (pixel) a fragment program (fragment shader) is executed

Shaders

```
// Vertex Shader
#version 420

layout(location = 0) in vec3 vertex; // x,y,z
layout(location = 1) in vec3 color; // r,g,b
out vec3 vsOutColor; // output result for this vertex
uniform mat4 modelViewProjectionMatrix;
```

```
void main()
{
    gl_Position = modelViewProjectionMatrix *
        vec4(vertex,1); //Project the vertex from 3D
    vsOutColor = color; // Output for this vertex. Will
                        // be interpolated input to
                        // fragment shader
}
```

```
// Fragment Shader:
#version 420
precision highp float; // 32-bits floats

in vec3 vsOutColor; // interpolated input
                    // from vertex shader
layout(location = 0) out vec4 fragColor;
// Here, location=0 means that we
// draw to framebuffer[0], i.e., the screen
```

```
void main()
{
    fragColor = vec4(vsOutColor,1);
}
```

Shaders

Example of a more advanced fragment shader:

```
precision highp float;

uniform sampler2D tex0;
uniform sampler2D tex1;
uniform sampler2D tex2;
uniform sampler2D tex3;

uniform float val;

varying vec2 uv_0;
varying vec3 n;

void main(void) {
    gl_FragColor.rgb =
        compute_color();
    gl_FragColor.a = 1.0;
}
```

```
vec3 compute_color()
{
    vec4 gbuffer = texture2D(tex0, uv_0);
    int intColor = int(gbuffer.x);
    int r = (intColor/256)/256;
    intColor -= r*256*256;
    int g = intColor/256;
    intColor -= g*256;
    int b = intColor;

    vec3 color = vec3(float(r)/255.0, float(g)/255.0,
        float(b)/255.0 );

    normal = vec3(sin(gbuffer.g) * cos(gbuffer.b),
        sin(gbuffer.g)*sin(gbuffer.b), cos(gbuffer.g));
    vec2 ang = gbuffer.gb*2.0-vec2(1.0);
    vec2 scth = vec2( sin(ang.x * PI), cos(ang.x * PI));
    vec2 scphi = vec2(sqrt(1.0 - ang.y*ang.y), ang.y);
    normal = -vec3(scth.y*scphi.x, scth.x*scphi.x,
        scphi.y);
    roughness = 0.05;
    specularity = 1.0;
    fresnelR0 = 0.3;
    return color;
}
```

OpenGL

(Open Graphics Library)

CPU-side

Language:

C++

API:

OpenGL (Direct3D)

Window system: SDL (Cocoa, Win32,...)

C++:

```
float positions[] = {  
// X      Y      Z      per vertex  
 0.0f,   0.5f,  1.0f, // v0  
-0.5f,  -0.5f,  1.0f, // v1  
 0.5f,  -0.5f,  1.0f // v2  
  ...  
 // ... vn  
};
```

// and any other per-vertex data, e.g.:

```
float colors[] = {  
// R      G      B  
 1.0f,   0.0f,  0.0f, // c0  
-0.0f,   1.0f,  0.0f, // c1  
 0.0f,   0.0f,  1.0f // c2  
  ...  
 // ... cn  
};
```

```
float normals[] = {...};
```

```
float textureCoords[] = {...};
```

OpenGL C++ API:

Vertex-buffer objects

```
uint32 positionBuffer; // x,y,z per vertex  
uint32 colorBuffer;   // r,g,b per vertex
```

Vertex-Array object // groups the arrays

```
uint32 vertexArrayObject;
```

Shaders

```
uint32 vertexShader;  
uint32 fragmentShader;  
uint32 shaderProgram;
```

GPU-side

Language: GLSL

used for vertex-, geometry-, and fragment shaders

Vertex Shader:

```
#version 420
```

```
layout(location = 0) in vec3 position;  
layout(location = 1) in vec3 color;
```

```
out vec3 outColor; // r,g,b
```

```
void main()
```

```
{  
    gl_Position = vec4(position, 1.0);  
    outColor = color;  
}
```

Fragment Shader:

```
#version 420
```

```
precision highp float; // required by GLSL spec Sect 4.5.3  
// (though nvidia does not, amd does)
```

```
layout(location = 0) out vec4 fragmentColor;  
in vec3 outColor; // Per-pixel-interpolated value
```

```
void main()
```

```
{  
    // fragmentColor = vec4(1,1,1,1);  
    fragmentColor.rgb = outColor;  
    fragmentColor.a = 1.0;  
}
```

CPU-side

Language: C++
 API: OpenGL (Direct3D)
 Window system: SDL (Cocoa, Win32,...)

C++:

```
float positions[] = {
// X      Y      Z
  0.0f,   0.5f,  1.0f, // v0
 -0.5f,  -0.5f,  1.0f, // v1
  0.5f,  -0.5f,  1.0f  // v2
```

How to connect the
 vertexArrayObject as vertex
 shader input (position, color):

```
0.00f,  0.00f,  1.00f // c2
...      // ... cn
};
```

```
float normals[] = {...};
float textureCoords[] = {...};
```

OpenGL C++ API:

Vertex-buffer objects

```
uint32 positionBuffer; // x,y,z per vertex
uint32 colorBuffer;    // r,g,b per vertex
```

```
Vertex-Array object // groups the arrays
uint32 vertexArrayObject;
```

Shaders

```
uint32 vertexShader;
uint32 fragmentShader;
uint32 shaderProgram;
```

GPU-side

Language: GLSL
 used for vertex-, geometry-, and
 fragment shaders

Vertex Shader:

```
#version 420

layout(location = 0) in vec3 position;
layout(location = 1) in vec3 color;

out vec3 outColor;

void main()
{
  gl_Position = vec4(position, 1.0);
  outColor = color;
}
```

```
glGenVertexArrays(1, &vertexArrayObject);
// Following commands now affect this vertex array object.
glBindVertexArray(vertexArrayObject);
```

```
// Makes positionBuffer the current array buffer for subse-
quent commands.
// and attaches positionBuffer to vertexArrayObject,
glBindBuffer( GL_ARRAY_BUFFER, positionBuffer );
// Connect positions to location 0. 3 floats per vertex
glVertexAttribPointer(0, 3, GL_FLOAT, ..., positions );
```

```
// Makes colorBuffer the current array buffer for subseque-
nt commands.
// and attaches colorBuffer to vertexArrayObject,
glBindBuffer( GL_ARRAY_BUFFER, colorBuffer );
// Connect colors to location 1. 3 floats per vertex
glVertexAttribPointer(1, 3, GL_FLOAT, ..., colors );
```

```
glEnableVertexAttribArray(0); // Enable attribute array 0
glEnableVertexAttribArray(1); // Enable attribute array 1
```

A Simple Program

Computer Graphics version of “Hello World”

Generate a triangle on a solid background

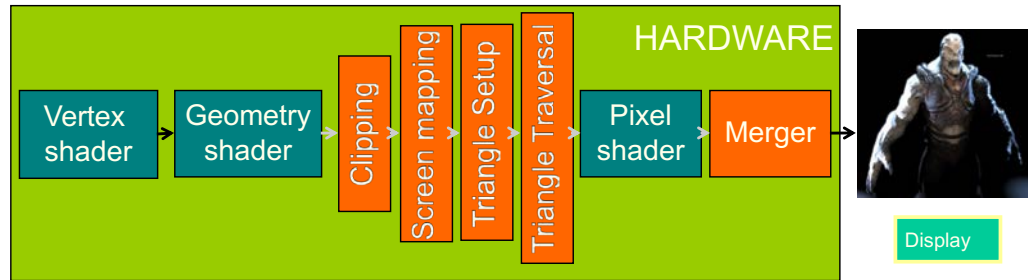

Graphics Pipelines

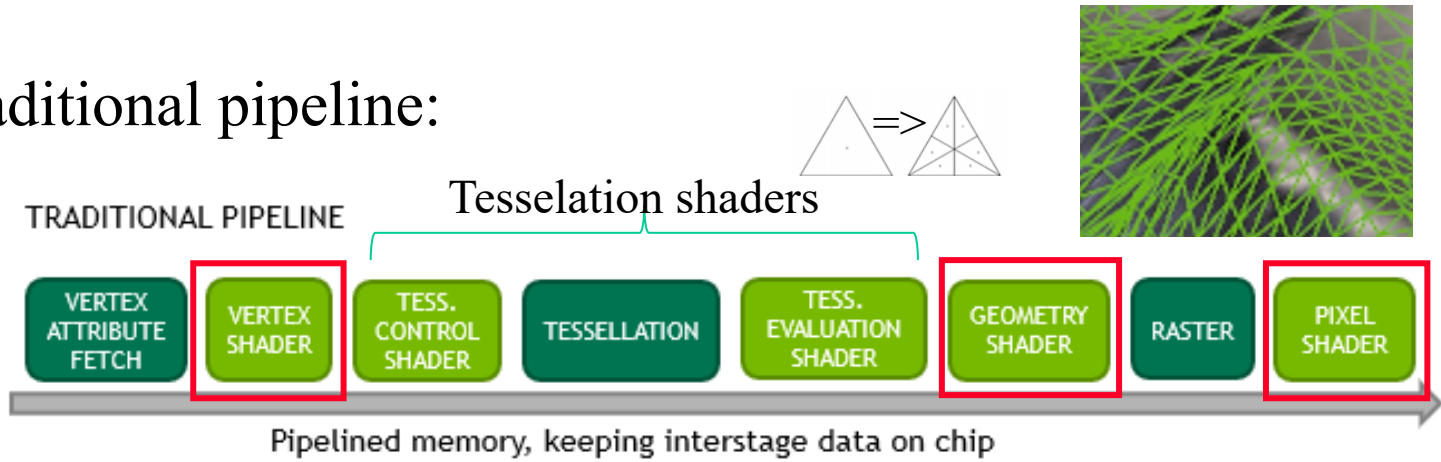

Compatibility:

- OpenGL 4.3
 - WebGL 2
 - OpenGL ES 3
- i.e., phones, web, PCs...

We focus on:

Full traditional pipeline:

Mesh shaders (still quite new):

Compatibility:

- OpenGL 4.5 extension
- DirectX 12 Ultimate
- Vulkan

Simple Application...

```
int main(int argc, char *argv[])
{
    // open window of size 512x512 with double buffering, RGB colors, and Z-buffering
    g_window = labhelper::init_window_SDL("OpenGL Lab 1", 512, 512);
    initGL(); // Set up our shaderProgram and our vertexArrayObject
    while (true) {

        display(); // render our geometry

        SDL_GL_SwapWindow(g_window); // swap front/back buffer. Ie., displays the frame.

        SDL_Event event;
        while (SDL_PollEvent(&event)) {
            if (event.type == SDL_QUIT || (event.type == SDL_KEYUP &&
                event.key.keysym.sym == SDLK_ESCAPE)) {
                labhelper::shutDown(g_window);
                return 0;
            }
        }
    }
    return 0;
}
```

```

void display(void)
{
    // The viewport determines how many pixels we are rasterizing to
    int w, h;
    SDL_GetWindowSize(g_window, &w, &h);
    glViewport(0, 0, w, h); // Set viewport

    // Clear background
    glClearColor(0.2, 0.2, 0.8, 1.0); // Set clear color - for background
    glClear(GL_COLOR_BUFFER_BIT | GL_DEPTH_BUFFER_BIT); // Clears the color buffer and the z-buffer

    glDisable(GL_CULL_FACE); // Both front and back face of triangles should be visible

    // DRAW OUR TRIANGLE(S)
    glUseProgram( shaderProgram ); // Shader Program. Sets what vertex/fragment shaders to use.
    // Bind the vertex array object that contains all the vertex data.
    glBindVertexArray(vertexArrayObject);
    // Submit triangles from currently bound vertex array object.
    glDrawArrays( GL_TRIANGLES, 0, 3 ); // Render 1 triangle (i.e., 3 vertices), starting at vertex 0.

    glUseProgram( 0 ); // "unsets" the current shader program. Not really necessary.
}

```

Lab 1 will teach you this, i.e., setting up a shader program and vertex arrays.

Example of a simple GfxObject class

```
class GfxObject {
public:
    load("filename"); // Creates m_shaderProgram + m_vertexArrayObject
    render()
    {
        /* You may want to initiate more OpenGL states, e.g., for
           textures (more on that in further lectures) */
        glUseProgram(m_shaderProgram);
        glBindVertexArray(m_vertexArrayObject);
        glDrawArrays( GL_TRIANGLES, 0, numVertices);
    };
private:
    uint        numVertices;
    GLuint      m_shaderProgram;
    GLuint      m_vertexArrayObject;
};
```

Example:

```
GfxObject myCoolObject;
myCoolObject.load("filename");
```

```
In display():
    myCoolObject.render();
```

The Geometry stage and
Rasterizer stage
in more detail

Rewind!

Let's take a closer look

- The programmer "sends" down primitives to be rendered through the pipeline (using API calls)
- The geometry stage does per-vertex operations
- The rasterizer stage does per-pixel operations
- Next, scrutinize geometry and rasterizer

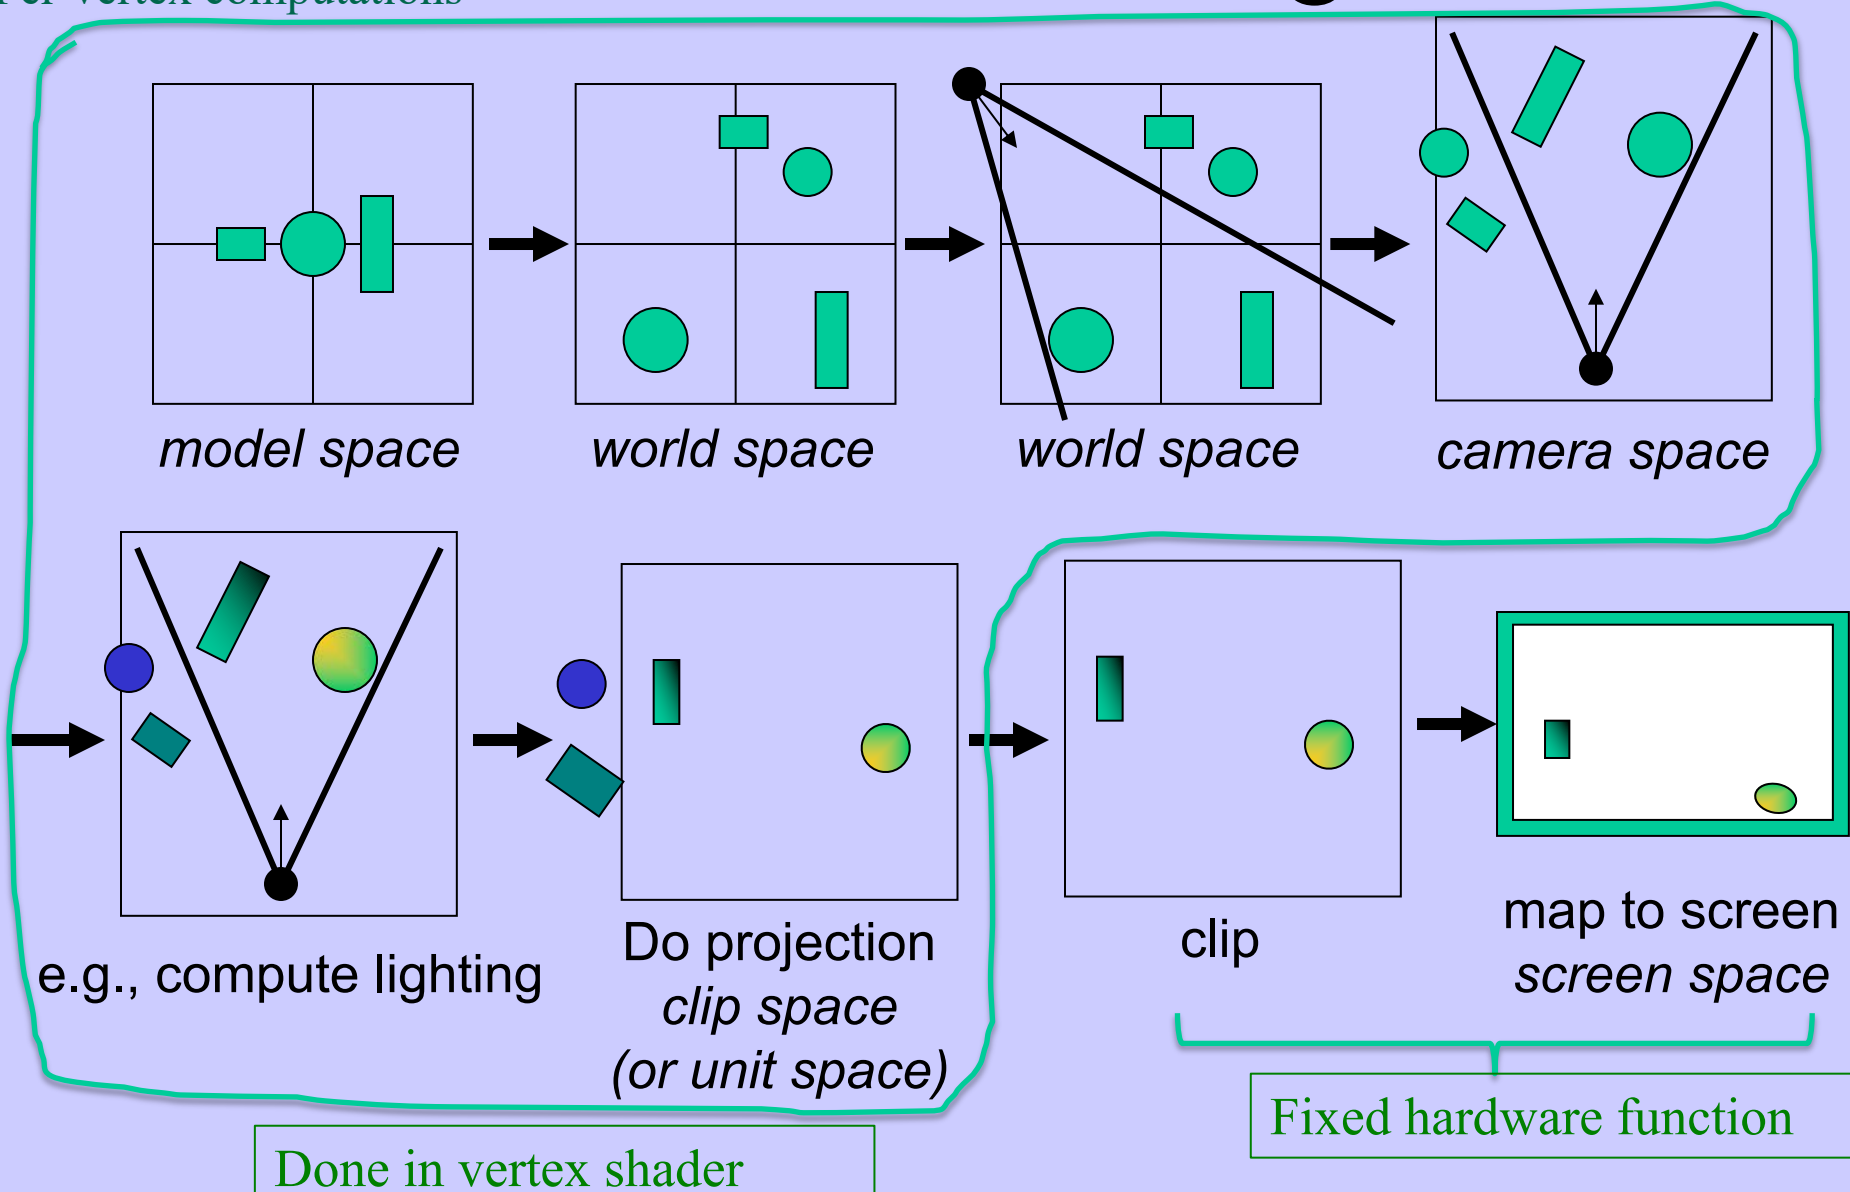

Application

Geometry

Rasterizer

GEOMETRY Stage

Per-vertex computations

Virtual Camera

- Defined by position, direction vector, up vector, field of view, near and far plane.

- Create image of geometry inside gray region
- Used by OpenGL, DirectX, ray tracing, etc.

GEOMETRY - The view transform

- You can move the camera in the same manner as objects
- But apply inverse transform to objects, so that camera looks down negative z-axis

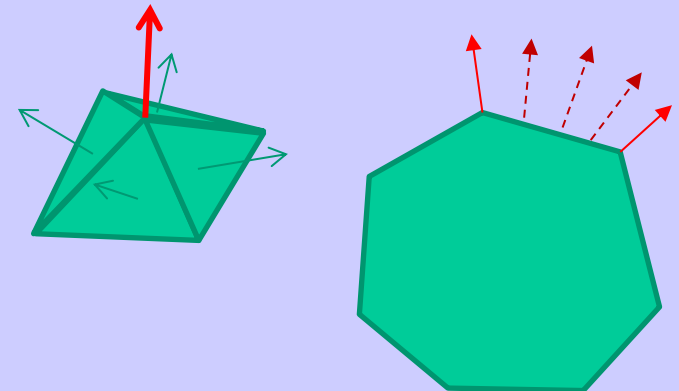

GEOMETRY - Lighting

- Compute "lighting" at vertices

- Try to mimic how light in nature behaves
 - Hard so uses empirical models, hacks, and some real theory
- Much more about this in later lecture

Why a normal per vertex?

GEOMETRY - Projection

- Two major ways to do it
 - Orthogonal (useful in few applications)
 - Perspective (most often used)
 - Mimics how humans perceive the world, i.e., objects' apparent size decreases with distance

GEOMETRY - Projection

- Also done with a matrix multiplication!
- Pinhole camera (left), analog used in CG (right)

GEOMETRY

Application

Geometry

Rasterizer

Clipping and Screen Mapping

- Square (cube) after projection
- Clip primitives to square

- Screen mapping, scales and translates the square so that it ends up in a rendering window
- These "screen space coordinates" together with Z (depth) are sent to the rasterizer stage

The rasterizer stage

Merging - output color to screen:
includes for instance...

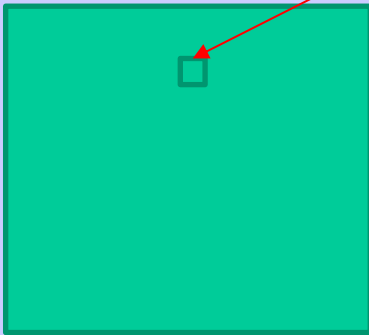

- **Z-buffering**
 - Do not overdraw a pixel with content that is further from the camera than the pixel's current content
- **Doublebuffering**

The default frame buffer:

Typically: Front + Back color buffers + Z buffer + (Stencil buffer)

These are memory buffers, e.g., in GPU RAM.

Stores rgb(a) value per pixel.
Default: 8 bits per r,g,b channel.

Front Color buffer
(rgb buffer)

Is the last fully
finished drawn frame.
Is displayed.

Back Color buffer
(rgb buffer)

Is the color buffer we
draw to.
Not displayed yet.

Stores fragment's
depth value per
pixel, typically: (16),
24, or 32 bits.

Z buffer
(depth)

To resolve visibility
between triangles

Stencil buffer can be
asked for. 8-bits per
pixel.

Stencil buffer
(8-bits)

Used for masking rendering
to only where pixel's stencil
value = some specific value.

The RASTERIZER

Application

Geometry

Rasterizer

Z-buffering

- A triangle that is covered by a more closely located triangle should not be visible
- Assume two equally large tris at different depths

Triangle 1

Triangle 2

Draw 1 then 2

Draw 2 then 1

The RASTERIZER

Application

Geometry

Rasterizer

Z-buffering

- Would be nice to avoid sorting...
- The Z-buffer (aka depth buffer) solves this
- Can render in any order

Idea - storing closest fragment-z (triangle depth) at each pixel:

- When rasterizing a triangle, compute fragment's z-value.
- Compare triangle's z to Z-buffer z-value
- If triangle's z is smaller, then replace Z-buffer's and color buffer's value
- Else do nothing (discard the fragment)

- Z-buffer stores, for each pixel, the closest fragment's z-value.
- Color buffer stores, for each pixel, the color value.

I.e., do not overdraw a pixel with content that is further from the camera than its current content

The RASTERIZER

Z-buffer

The color buffer

The z-buffer
(or depth buffer)

The RASTERIZER

Z-buffer

Painter's Algorithm

- Render polygons a back to front order so that polygons behind others are simply painted over

B behind A as seen by viewer

Fill B then A

- Requires ordering of polygons first
 - $O(n \log n)$ calculation for ordering
 - Not every polygon is either in front or behind all other polygons

I.e., : Sort all triangles and render them back-to-front.

Z-Buffer Algorithm

- Use a buffer called the z or depth buffer to store the depth of the closest object at each pixel found so far
- As we render each polygon, compare the depth of each new fragment, d_{new} , to depth in z buffer, d_{zb}
- If $d_{new} < d_{zb}$ (new fragment is closer to cam), replace pixel's color and z-buffer value.

The RASTERIZER

double-buffering

Application

Geometry

Rasterizer

- We do not want to show the image until its drawing is finished.

Front buffer
(rgb color buffer)

Back buffer
(rgb color buffer)

- The front buffer is displayed
- The back buffer is rendered to
- When new image has been created in back buffer, swap the Front-/Back-buffer pointers.
- Use vsynch or screen tearing will occur...

i.e., when the swap happens in the middle of the screen with respect to the screen refresh rate.

Last fully finished
drawn frame.

Color buffer we draw to.
Not displayed yet.

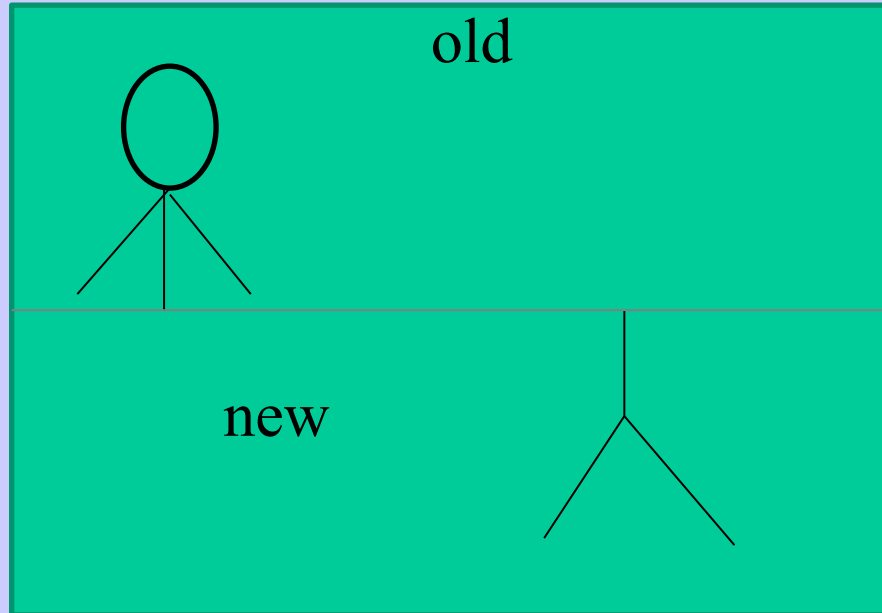

The RASTERIZER

Application

Geometry

Rasterizer

double-buffering – screen tearing

Example if the swap happens here (w.r.t the screen refresh rate).
Solution: use vsynch to swap buffers after monitor has "updated" the screen. See page 1011-1012.

Screen Tearing

Swapping
back/front buffers

Screen tearing is solved by using V-Sync.

vblank →

V-Sync: swap front/back buffers during vertical blank (vblank) instead.

Screen Tearing

- Despite the gorgeous graphics seen in many of today's games, there are still some highly distracting artifacts that appear in gameplay despite our best efforts to suppress them. The most jarring of these is screen tearing. Tearing is easily observed when the mouse is panned from side to side. The result is that the screen appears to be torn between multiple frames with an intense flickering effect. Tearing tends to be aggravated when the framerate is high since a large number of frames are in flight at a given time, causing multiple bands of tearing.
- **Vertical sync (V-Sync) is the traditional remedy to this problem,** but as many gamers know, V-Sync isn't without its problems. The main problem with V-Sync is that when the framerate drops below the monitor's refresh rate (typically 60 fps), the framerate drops disproportionately. For example, dropping slightly below 60 fps results in the framerate dropping to 30 fps. This happens because the monitor refreshes at fixed intervals (although an LCD doesn't have this limitation, the GPU must treat it as a CRT to maintain backward compatibility) and V-Sync forces the GPU to wait for the next refresh before updating the screen with a new image. This results in notable stuttering when the framerate dips below 60, even if just momentarily.

A Swap Chain

Tripple buffering - or even more intermediate buffers

So, GPU does not have to wait until the swap for starting rendering the next frame.

What is important:

- Understand the Application-, Geometry- and Rasterization Stage
- Correlation to hardware
- Z-buffering, double buffering, screen tearing

Simple Application...

OLD WAY

OpenGL 1.1

```
#ifdef WIN32
#include <windows.h>
#endif
```

```
#include <GL/glut.h>
```

// This also includes gl.h

```
static void drawScene(void)
{
    glColor3f(1,1,1);

    glBegin(GL_POLYGON);
        glVertex3f( 4.0, 0, 4.0);
        glVertex3f( 4.0, 0,-4.0);
        glVertex3f(-4.0, 0,-4.0);
    glEnd();
}
```

Usually this and next 2 slides are put in the same file main.cpp

Simple Application

BONUS
Old way
OpenGL 1.1

```
void display(void)
{
    glClearColor(0.2, 0.2, 0.8, 1.0);          // Set clear color
    glClear(GL_COLOR_BUFFER_BIT | GL_DEPTH_BUFFER_BIT); // Clears the color buffer
                                                    and the z-buffer

    int w = glutGet((GLenum)GLUT_WINDOW_WIDTH);
    int h = glutGet((GLenum)GLUT_WINDOW_HEIGHT);
    glViewport(0, 0, w, h);                    // Set viewport

    glMatrixMode(GL_PROJECTION);              // Set projection matrix
    glLoadIdentity();
    gluPerspective(45.0,w/h, 0.2, 10000.0); // FOV, aspect ratio, near, far

    glMatrixMode(GL_MODELVIEW);              // Set modelview matrix
    glLoadIdentity();

    gluLookAt(10, 10, 10,                     // look from
              0, 0, 0,                         // look at
              0, 0, 1);                       // up vector

    drawScene();
    glutSwapBuffers(); // swap front and back buffer. This frame will now been displayed.
}
```

Changing Color per Vertex

BONUS
Old way
OpenGL 1.1

```
static void drawScene(void)
{
    // glColor3f(1,1,1);
    glBegin(GL_POLYGON);
        glColor3f(1,0,0);
        glVertex3f( 4.0, 0, 4.0);

        glColor3f(0,1,0);
        glVertex3f( 4.0, 0,-4.0);

        glColor3f(0,0,1);
        glVertex3f(-4.0, 0,-4.0);
    glEnd();
}
```
