Model-Based Testing
(DIT848 / DAT260)
Spring 2012

Lecture 1
Overview of Verification and Validation

Gerardo Schneider
Dept. of Computer Science and Engineering
Chalmers | University of Gothenburg

Some slides based on material by Magnus Björk, Thomas Arts and Ian Somerville)

Lecture 1

- Introduce software verification and validation and discuss the distinction between them

- Introduce link between development and test

Lots of new words, putting them into context

Discuss: What is SW quality?

Quality aspects considered in this course

High priority

- Correctness:
  - The program should fulfill its specification
  - The program should not malfunction (crash, etc)

Lower priority

- Suitability

- Usefulness

- Code maintainability / standards conformance

- Document quality

# Motivation

Product development costs

How much do you think testing "costs"?

Motivation

Product development costs (Sommerville)

0%   100%

> 50%

specification   development   System testing

The more mature innovations get, the more important is their quality

Software quality is getting a competitive distinction

The company being able to test better for less money gets the market

Bugs are serious

Ariane 5 flight 501
- Error in a code converting 64-bit floating-point numbers into 16-bit signed integer. It triggered an overflow condition
- rocket disintegrate 40 seconds after launch
- Price: ~USD 370M in equipment

- Therac-25 Radiation therapy machine
  - It was possible to configure the Therac-25 so the electron beam would fire in high-power mode but with the metal X-ray target out of position
  - Source of error: a "race condition"
  - Price: 5 people killed by massive overdoses

Verification & Validation

- **Verification**:
     "Are we building the product right"

The software should conform to its specification

- **Validation**:
     "Are we building the right product"

The software should do what the user really requires

V model [cf Spillner 2000]

Requirements → Acceptance Test

Specification → System Test

Architectural Design → Integration Test

Detailed Design → Unit Test

Coding

Validation

Verification

Not necessarily chronological. Usually built up iteratively.

How does it work in practice?

- This is what we will see in this course

- Remember that the V-model is useful to show how development and test are related conceptually
  - In practice, different ways to organize/perform testing

- We will see "traditional" ways of performing testing

- And obviously Model-Based Testing (MBT)

Dynamic and static verification

- *DYNAMIC*
  - *Software testing* & Runtime verification
    - Concerned with exercising and observing product behaviour
    - The system is executed with test data and its operational behaviour is observed

- *STATIC*
  - *Software inspections* & Other model-based techniques
    - Concerned with analysis of the static system (representation) to discover problems
    - May be supplemented by tool-based document and analysis

The V&V process

- Is a whole life-cycle process
  - V&V must be applied at each stage in the software process
  - So, V&V and development processes depend on each other

- Has two principal objectives
  - The discovery of defects in a system
  - The assessment of whether or not the system is useful and useable in an operational situation
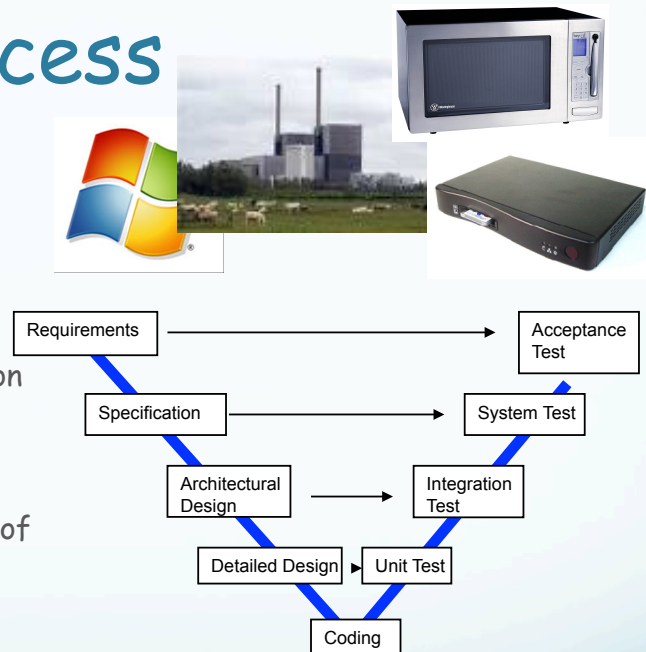

V&V process

Goals

- Verification and validation should **increase confidence** on that the software fits the intended purpose

- This does NOT mean completely free of defects

- Rather, it must be good enough for its intended use and the type of use will determine the degree of confidence that is needed

---

V&V process

Confidence

Depends on

- Software function
  - The level of confidence depends on how critical the software is to an organisation

- User expectations
  - Users may have low expectations of certain kinds of software

- Marketing environment
  - Getting a product to market early may be more important than finding defects in the program

- Patchability
  - Can sold units be upgraded easily?

Requirements	→	Acceptance Test
Specification	→	System Test
Architectural Design	→	Integration Test
Detailed Design	→	Unit Test
Coding		

Discussion

Software testing automobiles

Discuss software in the car

Discuss for several software
components:

- How critical they are

- What the users expect

- How the marketing environment
looks like

- Whether upgrades are feasible

Offset crash test at 64km/h

V&V planning

- Careful planning is required to get the most out of static
and dynamic verification

- **Planning should start early in the development process**

- The plan should identify the balance between dynamic
and static "verification" (between testing and inspection)

- V&V planning is about defining standards for the V&V
process, rather than describing product tests

- **The more critical the system, the more effort should
be devoted to static verification**

V&V planning

Plan V&V process

- Which activities?

- Which results for each activity?

- Who performs activity?

V-model helps to connect test activities to development activities

Each development activity corresponds to a test level

Test levels

Test level: A group of test activities that are organized and managed together

A test level is linked to responsibilities in a project

For each level, it is important to test what was not possible to verify or validate on lower levels

Different methods and techniques may apply to each level

Verification and Validation

Requirements → Acceptance Test

Specification → System Test

Architectural Design → Integration Test

Detailed Design → Unit Test

Coding

Verification and Validation

Specification → System V&V planning → System Test

Static verification ← ... → Validation Dynamic Verification

Use of Formal Methods?

Dynamic verification

- **Testing** can reveal the presence of errors NOT their absence (Dijkstra 1960ies)

- The "only" validation technique for non-functional requirements as the software has to be executed to see how it behaves
  - Non-exhaustive

- Should be used in conjunction with **static verification** to provide full V&V coverage

Types of testing (one possible classification)

- **Defect testing**
  - Tests designed to discover system defects
  - A successful defect test is one which reveals the presence of defects in a system

- **Validation testing**
  - *Quality assurance process* carried out before the software is ready for release
  - Intended to show that the software meets the requirements given by the user
    - Acceptance by the end user
  - A successful test is one that shows that requirements have been properly implemented

Testing and debugging

- Defect testing and debugging are distinct processes

- Testing is concerned with establishing the existence of defects in a program

- Debugging is concerned with locating and repairing these errors
  - Debugging involves formulating a hypothesis about program behaviour then testing these hypotheses to find the system error

Costs of debugging are often included in costs for Software Testing

Software inspections

Software inspection is a manual static verification method

- It involves people/tools examining the source representation with the aim of discovering anomalies and defects

- Inspections can take place on all development levels, no matter the formality of the sources

- Inspections do not require execution of a system so may be used before implementation

- They may be applied to any representation of the system (requirements, design, configuration data, test data, etc.)

- Shown to be an effective technique for discovering program errors

XP: pair programming

Inspection success

- Many different defects may be discovered in a single inspection
  - In testing, one defect may mask another so several executions are required

- They reuse domain and programming knowledge so reviewers are likely to have seen the types of error that commonly arise

- Incomplete versions of a system can be inspected without extra cost

- You can look for inefficiencies, poor programming style, etc

Inspections and testing

- Inspections and testing are complementary and not opposing verification techniques

- Both should be used during the V&V process

- Inspections can check conformance with a specification but **not** conformance with the customer's real requirements

- Inspections **cannot** check non-functional characteristics such as performance, usability, etc.

- But inspections can find other non-functional characteristics such as standards compliance of code

Verification and formal methods

- Formal methods can be used when a mathematical specification of the system is known

- They are the *ultimate* verification technique

- They involve detailed mathematical analysis of the specification and may develop formal arguments that a program conforms to its mathematical specification
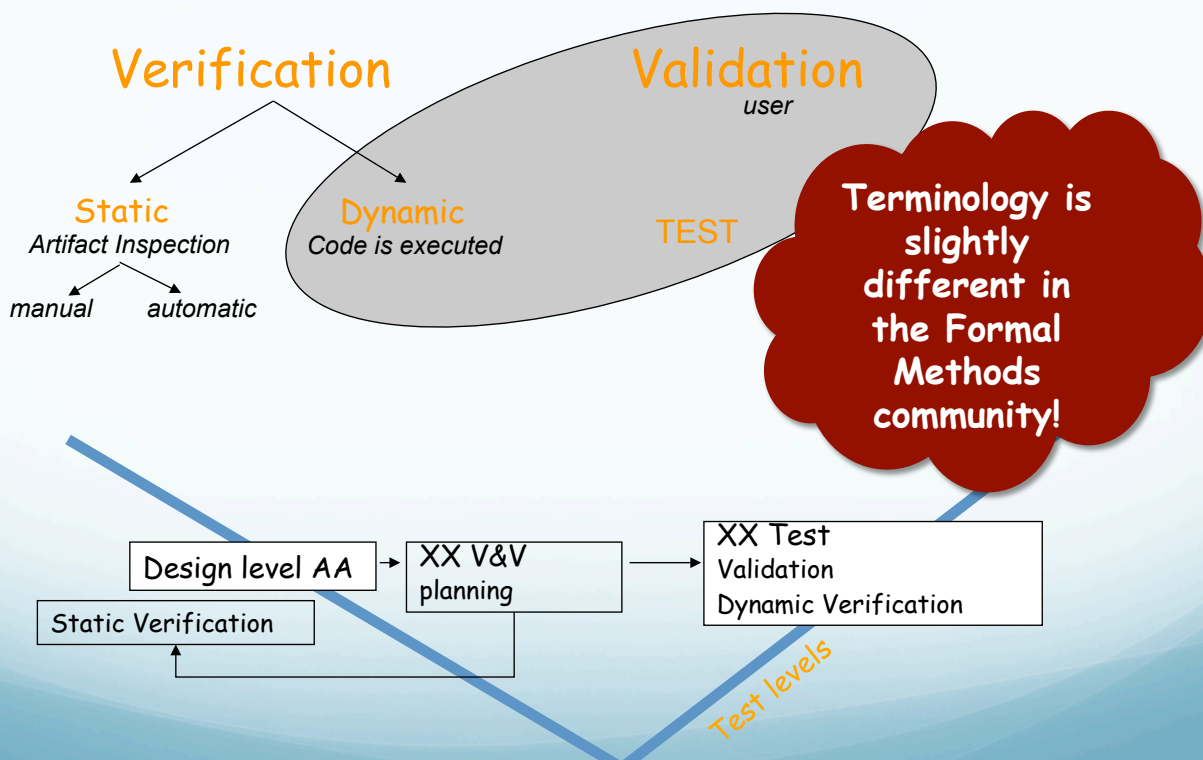

Typical testing methods on each level

- Unit tests:
  - Each programmer required to write unit tests for own code, organized in automatically executable tests suite
  - Automatic static verification (lint/splint-like)
  - Manual code inspections

- Integration tests:
  - Write test cases that monitor how modules interact
  - Some manual code inspections

- System tests:
  - Scripted test suite (especially if text based program)
  - Manual tests – trying to break the system

- Acceptance tests:
  - Customer manually tests software

Model-Based testing (automatic test extraction from a model) not specifically associated with a level – need of a model!

Conclusions

- **Verification** and **validation** are not the same thing
  - **Verification** shows conformance with specification;
  - **Validation** shows that the program meets the customer's needs

- V&V plans should be drawn up to guide the V&V process (part of the V&V plan is a test plan)

- Each design activity has a corresponding V&V activity

- **Static verification** techniques involve examination and analysis for error detection (among others)

- **Dynamic verification** implies "running" the code

Terminology

Verification   Validation
             user

Static
Artifact Inspection

manual   *automatic*

Dynamic
Code is executed

TEST

Terminology is slightly different in the Formal Methods community!

Design level AA → XX V&V planning → XX Test / Validation / Dynamic Verification

Static Verification

Test levels
