

Två saker

- Labsal bokning
 - Sprid ut er över salarna
- “Bracket Matching”

```
[ "<li>Slides: "
  ++ concat (intersperse ", "
| let gs = [ f | f <- sort fs
              , any (`isSuffixOf_,_
                  [ ".odp", ".ppt", ".pdf" ]
]
, not (null gs)
]
```

IO and Instructions

Koen Lindström Claessen

Apple Pie

Mumsig äppelpaj

Värmt upp ugnen till 225 grader, blanda ingredienserna nedan och se till att fatet är både ugnssäkert och insmort med margarin. Lägg på äpplena som du tärnar först och sen kanal och socker ovanpå. Häll på resten av smulpajen och låt stå i ugnen i ca 25 minuter. Servera med massor av vaniljsås!

2.5 dl mjöl

100 gram margarin

5-6 äpplen, gärna riktigt stora

1 dl socker

1 msk kanal

Mycket vaniljsås, gärna Marzan

Difference?

Running a Program

The image consists of two windows. The top-left window is titled "Function Graph" and contains a graph of a periodic, wavy function. Below the graph is a text input field containing the mathematical expression $30\sin(0.1x) + 5\cos x$. The top-right window is titled "Drawing Editor" and contains a wireframe drawing of a cube and several vertical lines. Two blue speech bubbles are positioned below the Function Graph window, pointing towards the input field. The left bubble asks, "How do you write this as a function?", and the right bubble asks, "What is the type of the result?".

Function Graph

30*sin(0.1*x)+5*cos x

How do you write this as a function?

What is the type of the result?

Drawing Editor

Undo Load Save

A Simple Example

```
Prelude> writeFile "myfile.txt" "Anna+Kalle=sant"
```

```
Prelude>
```

- Writes the text “Anna+Kalle=sant” to the file called “myfile.txt”
- No result displayed---why not?

What is the Type of writeFile?

```
Prelude> :i writeFile
writeFile :: FilePath -> String -> IO ()
```

Just a String

INSTRUCTIONS to the
operating system to write
the file

- When you give Haskell an expression of type `IO`, it *obeys the instructions* (instead of printing the result)

The type ()

- The type () is called the *unit type*
- It only has one value, namely ()
- We can see () as the “empty tuple”
- It means that there is no interesting result

The type FilePath

- Is a *type synonym*...
- ...which is a way to give a name to a type that already exists

```
type FilePath = String
```

- for convenience and/or documentation
- (Remember: **data** creates a *new type*, which is different

```
data Shape = Circle Float | ...
```

An Analogy

- Instructions:

1. Take this card
2. Put the card in the Bankomat
3. Enter the code “1437”
4. Select “500kr”
5. Take the money

- Value:

Which would
you rather have?

Värmt upp ugnen till 225 grader, blanda ingredienserna nedan och se till att fatet är både ugnssäkert och insmort med margarin. Lägg på äpplena som du tärnar först och sen kanal och socker ovanpå. Häll på resten av smulpajen och låt stå i ugnen i ca 25 minuter. Servera med massor av vaniljsås!

2.5 dl mjöl

100 gram margarin

5-6 äpplen, gärna riktigt stora

1 dl socker

1 msk kanal

Mycket vaniljsås, gärna Marzan

Which would
you rather have?

Instructions with a result value

```
Prelude> :i readFile  
readFile :: FilePath -> IO String
```

INSTRUCTIONS for
computing a String

- readFile “myfile.txt” is not a String
- no String can be extracted from it...
- ...but we can use it to create other instructions that use the result

We cannot extract 500kr
from the list of instructions
either...

Putting Instructions Together

```
writeTwoFiles :: FilePath -> String -> IO ()  
writeTwoFiles file s =  
  do writeFile (file ++ "1") s  
      writeFile (file ++ "2") s
```

Use **do** to combine instructions into larger ones

```
copyFile :: FilePath -> FilePath -> IO ()  
copyFile file1 file2 =  
  do s <- readFile file1  
      writeFile file2 s
```

Putting Instructions Together (2)

```
catFiles :: FilePath -> FilePath -> IO String
catFiles file1 file2 =
  do s1 <- readFile file1
     s2 <- readFile file2
     return (s1++s2)
```

Use **do** to combine instructions into larger ones

Use **return** to create an instruction with just a result

```
return :: a -> IO a
```

Instructions vs. Functions

- **Functions** always give the same result for the same arguments
- **Instructions** can behave differently on different occasions
- Confusing them is a major source of bugs
 - Most programming languages do so...
 - ...understanding the difference is important!

The IO type

```
data IO a -- a built-in type

putStr      :: String -> IO ()
putStrLn    :: String -> IO ()
readFile   :: FilePath -> IO String
writeFile  :: FilePath -> String -> IO ()
...
```

Look in the standard modules:
IO, System.IO, System.* , ...

Some Examples

- `doTwice :: IO a -> IO (a,a)`
- `dont :: IO a -> IO ()`
- `second :: [IO a] -> IO a`
- (see file `Instructions.hs`)

Evaluating & Executing

- IO actions of result type ()
 - are just executed

```
Prelude> writeFile "emails.txt" "anna@gmail.com"
```

- IO actions of other result types
 - are executed, and then the result is printed

```
Prelude> readFile "emails.txt"  
"anna@gmail.com"
```

Quiz

- Define the following function:

```
sortFile :: FilePath -> FilePath -> IO ()
```

- “`sortFile file1 file2`” reads the lines of `file1`, sorts them, and writes the result to `file2`
- You may use the following standard functions:

```
sort      :: Ord a => [a] -> [a]
lines    :: String -> [String]
unlines :: [String] -> String
```

Answer

```
sortFile :: FilePath -> FilePath -> IO ()
sortFile file1 file2 =
  do s <- readFile file1
     writeFile file2 (unlines (sort (lines s)))
```

An Example

- Let's define the following function:

```
getLine :: IO String
```

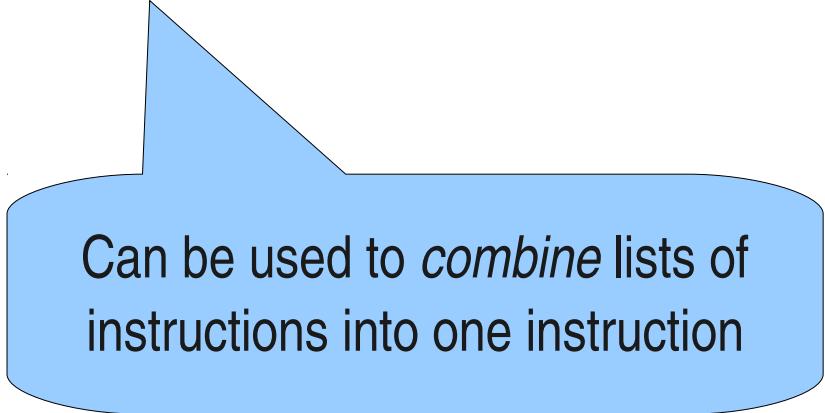

```
Prelude> getLine  
apa  
“apa”
```

- We may use the following standard function:

```
getChar :: IO Char
```

Two useful functions

```
sequence    :: [IO a] -> IO [a]
sequence_   :: [IO ()] -> IO ()
```

Can be used to *combine* lists of instructions into one instruction

An Example

- Let's define the following function:

```
writeFiles :: FilePath -> [String] -> IO ()
```

```
Prelude> writeFiles "file" ["apa","bepa","cepa"]
```

```
Prelude> readFile "file1"  
"apa"
```

```
Prelude> readFile "file3"  
"cepa"
```

- We may use the following standard functions:

```
show      :: Show a => a -> String  
zip      :: [a] -> [b] -> [(a,b)]
```

A possible definition

```
writeFiles :: FilePath -> [String] -> IO ()  
writeFiles file xs =  
  sequence_ [ writeFile (file++show i) x  
             | (x,i) <- zip xs [1..length xs]  
           ]
```

We create complex
instructions by combining
simple instructions

Definitions?

```
sequence_ :: [IO ()] -> IO ()
```

```
sequence :: [IO a] -> IO [a]
```

Functions vs. Instructions

- **Functions** always produce the same results for the same arguments
- **Instructions** can have varying results for each time they are executed
- Are these functions?

```
putStrLn :: String -> IO ()  
readFile :: FilePath -> IO String  
getLine :: IO String
```

YES! They deliver
the same instructions for the
same arguments

(but executing these
instructions can have
different results)

What is the Type of doTwice?

```
Prelude> :i doTwice
doTwice :: Monad m => m a -> m (a, a)
```

Monad = Instructions

There are several different kinds of instructions!

- We will see other kinds of instructions (than IO) in the next lecture

Reading

Chapter 9 of “Learn you a Haskell” on I/O

Do's and Don'ts

```
isBig :: Integer -> Bool  
isBig n | n > 9999 = True  
        | otherwise = False
```

guards and
boolean results

```
isBig :: Integer -> Bool  
isBig n = n > 9999
```

Do's and Don'ts

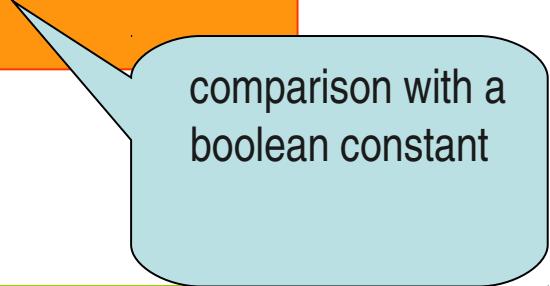

```
resultIsSmall :: Integer -> Bool  
resultIsSmall n = isSmall (f n) == True
```

comparison with a boolean constant

```
resultIsSmall :: Integer -> Bool  
resultIsSmall n = isSmall (f n)
```

Do's and Don'ts

```
resultIsBig :: Integer -> Bool  
resultIsBig n = isSmall (f n) == False
```

comparison with a
boolean constant

```
resultIsBig :: Integer -> Bool  
resultIsBig n = not (isSmall (f n))
```

and Don'ts

Do not make unnecessary case distinctions

```
fun1 :: [Integer] -> Bool  
fun1 []     = False  
fun1 (x:xs) = length (x:xs) == 10
```

necessary case distinction?

repeated code

```
fun1 :: [Integer] -> Bool  
fun1 xs = length xs == 10
```

Make the base case
as simple as possible

's and Don'ts

```
fun2 :: [Integer] -> Integer
fun2 [x]      = calc x
fun2 (x:xs) = calc x + fun2 xs
```

right base case ?

repeated code

```
fun2 :: [Integer] -> Integer
fun2 []      = 0
fun2 (x:xs) = calc x + fun2 xs
```
