

# Parallel & Distributed Real-Time Systems

Lecture #6

Professor Jan Jonsson

Department of Computer Science and Engineering Chalmers University of Technology

# Feasibility testing

#### What techniques for feasibility testing exist?

- Hyper-period analysis (for static and dynamic priorities)
  - In a simulated schedule no task execution may miss its deadline
- Guarantee bound analysis (for static and dynamic priorities)
  - The fraction of processor time that is used for executing the task set must not exceed a given bound
- Response time analysis (for static priorities)
  - The worst-case response time for each task must not exceed the deadline of the task
- Processor demand analysis (for dynamic priorities)
  - The accumulated computation demand for the task set under a given time interval must not exceed the length of the interval

# Feasibility testing

#### What techniques for feasibility testing exist?

- Hyper-period analysis (for static and dynamic priorities)
  - In a simulated schedule no task execution may miss its deadline
- Guarantee bound analysis (for static and dynamic priorities)
  - The fraction of processor time that is used for executing the task set must not exceed a given bound
- Response time analysis (for static priorities)
  - The worst-case response time for each task must not exceed the deadline of the task
- Processor demand analysis (for dynamic priorities)
  - The accumulated computation demand for the task set under a given time interval must not exceed the length of the interval

#### Response time:

• The <u>response time</u>  $R_i$  for a task  $\tau_i$  represents the worst-case completion time of the task when execution interference from other tasks are accounted for.

The response time for a task  $\tau_i$  consists of:

- $C_i$  The task's uninterrupted execution time (WCET)
- $I_i$  Interference from higher-priority tasks

$$R_i = C_i + I_i$$

#### Interference:

For static-priority scheduling, the interference term is

$$I_i = \sum_{\forall j \in hp(i)} \left[ \frac{R_i}{T_j} \right] C_j$$

where hp(i) is the set of tasks with higher priority than  $\tau_i$ .

• The response time for a task  $\tau_i$  is thus:

$$R_i = C_i + \sum_{\forall j \in hp(i)} \left\lceil \frac{R_i}{T_j} \right\rceil C_j$$

#### Response-time calculation:

- The equation does not have a simple analytic solution.
- However, an <u>iterative</u> procedure can be used:

$$R_i^{n+1} = C_i + \sum_{\forall j \in hp(i)} \left\lceil \frac{R_i^n}{T_j} \right\rceil C_j$$

- The iteration starts with a value that is guaranteed to be less than or equal to the final value of  $R_i$  (e.g.  $R_i^0 = C_i$ )
- The iteration completes at convergence  $(R_i^{n+1} = R_i^n)$  or if the response time exceeds the deadline  $D_i$

Schedulability test: (Joseph & Pandya, 1986)

An <u>exact</u> condition for static-priority scheduling is

$$\forall i : R_i \leq D_i$$

The test is only valid if all of the following conditions apply:

- 1. Single-processor system
- 2. Synchronous task sets
- 3. Independent tasks
- 4. Periodic tasks
- 5. Tasks have deadlines not exceeding the period  $(D_i \leq T_i)$

#### Time complexity:

Response-time analysis has pseudo-polynomial time complexity

#### Proof:

calculating the response-time for task  $au_i$  requires no more than  $D_i$  iterations

since  $D_i \leq T_i$  the number of iterations needed to calculate the response-time for task  $\tau_i$  is bounded above by  $T_i$ 

the procedure for calculating the response-time for all tasks is therefore of time complexity  $O(\max\{T_i\})$ 

the longest period of a task is also the largest number in the problem instance

#### Accounting for blocking:

- Blocking caused by critical regions
  - Blocking factor  $B_i$  represents the length of critical region(s) that are executed by processes with lower priority than  $\tau_i$
- Blocking caused by non-preemptive scheduling
  - Blocking factor  $B_i$  represents largest WCET (not counting  $\tau_i$ )

$$R_i = C_i + \mathbf{B}_i + \sum_{\forall j \in hp(i)} \left\lceil \frac{R_i}{T_j} \right\rceil C_j$$

Observation: the feasibility test is now only <u>sufficient</u> since the worst-case blocking will not always occur at run-time.

Accounting for blocking: (using PCP or ICPP)

When using priority ceiling a task  $\tau_i$  can only be blocked once by a task with lower priority than  $\tau_i$ .

This occurs if the lower-priority task is within a critical region when  $\tau_i$  arrives, and the critical region's ceiling priority is higher than or equal to the priority of  $\tau_i$ .

Blocking now means that the start time of  $\tau_i$  is delayed (= the blocking factor  $B_i$ )

As soon as  $\tau_i$  has started its execution, it cannot be blocked by a lower-priority task.

Accounting for blocking: (using PCP or ICPP)

Determining the blocking factor for  $\tau_i$ 

- 1. Determine the ceiling priorities for all critical regions.
- 2. Identify the tasks that have a priority lower than  $\tau_i$  and that calls critical regions with a ceiling priority equal to or higher than the priority of  $\tau_i$ .
- 3. Consider the times that these tasks lock the actual critical regions. The longest of those times constitutes the blocking factor  $B_i$ .

# (this page intentionally left blank)

#### Processor demand:

• The <u>processor demand</u> for a task  $\tau_i$  in a given time interval [0, L] is the amount of processor time that the task needs in the interval in order to meet the deadlines that fall within the interval.

Let  $N_i^L$  represent the number of instances of  $\tau_i$  that must complete execution before L.

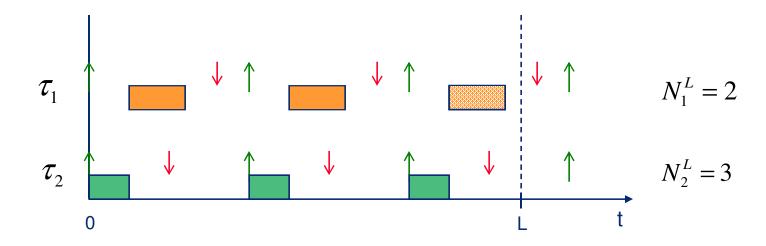

The total processor demand up to L is

$$C_P(0,L) = \sum_{i=1}^n N_i^L C_i$$

#### Number of relevant task arrivals:

• We can calculate  $N_i^L$  by counting how many times task  $\tau_i$  has arrived during the interval  $[0, L-D_i]$ .

We can ignore instance of the task that has arrived during the interval  $[L-D_i, L]$  since  $D_i > L$  for these instances.

#### Processor-demand analysis:

• We can express  $N_i^L$  as

$$N_i^L = \left\lfloor \frac{L - D_i}{T_i} \right\rfloor + 1$$

The total processor demand is thus

$$C_P(0,L) = \sum_{i=1}^n \left( \left\lfloor \frac{L - D_i}{T_i} \right\rfloor + 1 \right) C_i$$

Schedulability test: (Baruah et al., 1990)

A <u>sufficient and necessary</u> condition for EDF scheduling is

$$\forall L \in K : C_P(0,L) \leq L$$

The test is only valid if all of the following conditions apply:

- 1. Single-processor system
- 2. Synchronous task sets
- 3. Independent tasks
- 4. Periodic tasks
- 5. Tasks have deadlines not exceeding the period  $(D_i \le T_i)$

Schedulability test: (Baruah et al., 1990)

The set of control points K is

$$K = \left\{ D_i^k \mid D_i^k = kT_i + D_i, \ D_i^k \le L_{\max}, \ 1 \le i \le n, \ k \ge 0 \right\}$$

$$L_{\max} = \max \left\{ D_1, \dots, D_n, \frac{\sum_{i=1}^n (T_i - D_i) U_i}{1 - U} \right\}$$

#### Observation:

$$L_{\max} \leq \max \left\{ \max \left\{ D_i \right\}, \frac{U}{1 - U} \max \left\{ T_i - D_i \right\} \right\} \leq \max \left\{ \max \left\{ T_i \right\}, \frac{U}{1 - U} \max \left\{ T_i \right\} \right\}$$

#### Time complexity:

Processor-demand analysis has pseudo-polynomial time complexity if total task utilization is less than 100%

#### Proof:

the number of control points needed to check the processor demand is bounded above by

$$Q_L^{\max} = \max\left\{\max\left\{T_i\right\}, \frac{U}{1-U}\max\left\{T_i\right\}\right\} = \max\left\{1, \frac{U}{1-U}\right\} \max\left\{T_i\right\}$$

since U/(1-U) is a constant the procedure for calculating the processor demand is therefore of time complexity  $O(\max\{T_i\})$  the longest period of a task is also the largest number in the problem instance

Accounting for blocking: (using Stack Resource Policy)

Tasks are assigned static <u>preemption levels</u>:

The preemption level of task  $au_i$  is denoted  $au_i$ 

Task  $\tau_i$  is not allowed to preempt another task  $\tau_j$  unless  $\pi_i > \pi_j$  If  $\tau_i$  has higher priority than  $\tau_j$  and arrives later, then  $\tau_i$  must have a higher preemption level than  $\tau_j$ .

#### Note:

- The preemption levels are static values, even though the tasks priorities may be dynamic.
- For EDF scheduling, suitable levels can be derived if tasks with shorter relative deadlines get higher preemption levels, that is:

$$\pi_i > \pi_j \iff D_i < D_j$$

Accounting for blocking: (using Stack Resource Policy)

Resources are assigned dynamic <u>resource ceilings</u>:

Each shared resource is assigned a ceiling that is always equal to the maximum preemption level among all tasks that may be blocked when requesting the resource.

The protocol keeps a <u>system-wide ceiling</u> that is equal to the maximum of the current ceilings of all resources.

A task with the earliest deadline is allowed to preempt only if its preemption level is higher than the system-wide ceiling.

#### Note:

The original priority of the task is not changed at run-time.

The resource ceiling is a <u>dynamic</u> value calculated at run-time as a function of current resource availability.

Accounting for blocking: (using Stack Resource Policy)

Blocking factor  $B_i$  represents the length of critical / non-preemptive regions that are executed by tasks with lower preemption levels than  $\tau_i$ 

Tasks are indexed in the order of increasing preemption levels, that is:  $\pi_i > \pi_i \Leftrightarrow i < j$ 

$$\forall L \in K, \forall i \in [1, n]: C_P^i(0, L) \leq L$$

$$C_P^i = \sum_{k=1}^i \left( \left\lfloor \frac{L - D_k}{T_k} \right\rfloor + 1 \right) C_k + \left( \left\lfloor \frac{L - D_i}{T_i} \right\rfloor + 1 \right) B_i$$

Accounting for blocking: (using Stack Resource Policy)

Determining the blocking factor for  $\tau_i$ 

- 1. Determine the worst-case resource ceiling for each critical region, that is, assume the run-time situation where the corresponding resource is unavailable.
- 2. Identify the tasks that have a preemption level lower than  $\tau$  and that calls critical regions with a worst-case resource ceiling equal to or higher than the preemption level of  $\tau$ .
- 3. Consider the times that these tasks lock the actual critical regions. The longest of those times constitutes the blocking factor  $B_i$ .
