Computer
Networking: A Top
Down Approach

7th edition
Jim Kurose, Keith Ross
Pearson/Addison Wesley
April 2016

Network Layer: Control Plane 5-1

Link layer, LANs: outline

6.4 LANs

- addressing, ARP
- Ethernet
- switches
- VLANS

- 6.6 data center networking
- 6.7 a day in the life of a web request

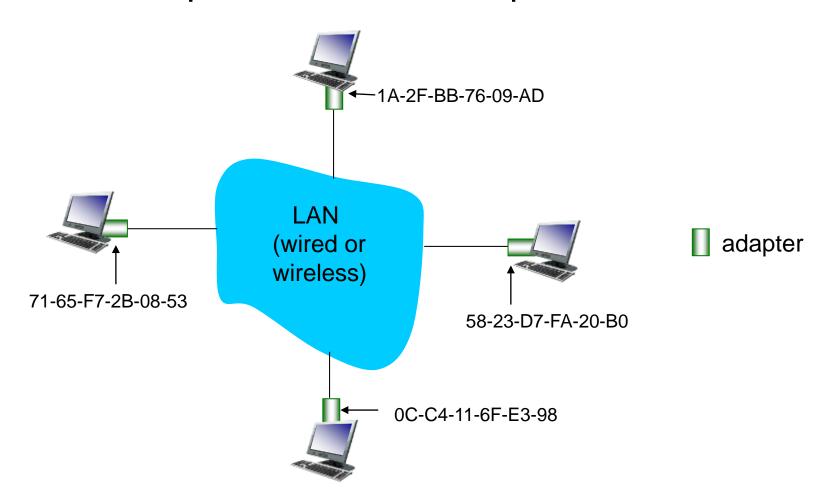

MAC addresses and ARP

- 32-bit IP address:
 - network-layer address for interface
 - used for layer 3 (network layer) forwarding
- MAC (or LAN or physical or Ethernet) address:
 - function: used 'locally" to get frame from one interface to another physically-connected interface (same network, in IP-addressing sense)
 - 48 bit MAC address (for most LANs) burned in NIC ROM, also sometimes software settable
 - e.g.: IA-2F-BB-76-09-AD

hexadecimal (base 16) notation (each "numeral" represents 4 bits)

LAN addresses and ARP

each adapter on LAN has unique LAN address

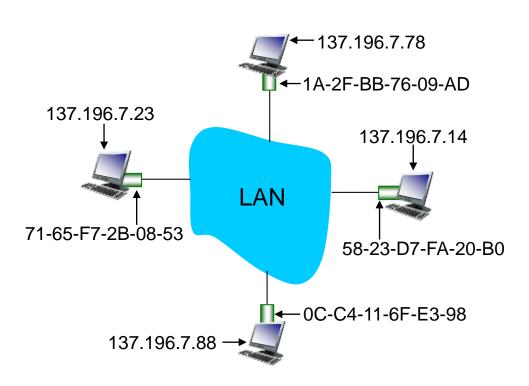

LAN addresses (more)

- MAC address allocation administered by IEEE
- manufacturer buys portion of MAC address space (to assure uniqueness)
- analogy:
 - MAC address: like Social Security Number
 - IP address: like postal address
- MAC flat address → portability
 - can move LAN card from one LAN to another
- IP hierarchical address not portable
 - address depends on IP subnet to which node is attached

ARP: address resolution protocol

Question: how to determine interface's MAC address, knowing its IP address?

ARP table: each IP node (host, router) on LAN has table

- IP/MAC address mappings for some LAN nodes:
 - < IP address; MAC address; TTL>
- TTL (Time To Live): time after which address mapping will be forgotten (typically 20 min)

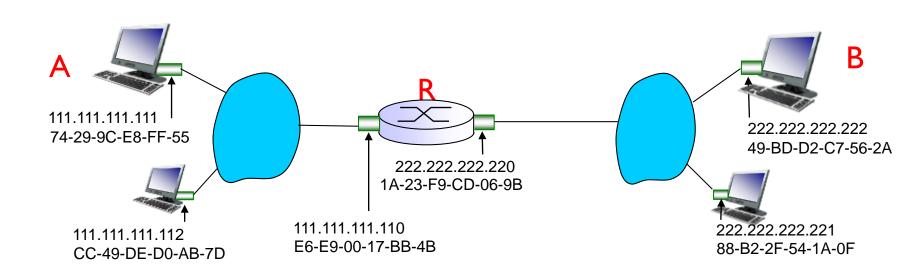

ARP protocol: same LAN

- A wants to send datagram to B
 - B's MAC address not in A's ARP table.
- A broadcasts ARP query packet, containing B's IP address
 - destination MAC address = FF-FF-FF-FF-FF
 - all nodes on LAN receive ARP query
- B receives ARP packet, replies to A with its (B's) MAC address
 - frame sent to A's MAC address (unicast)

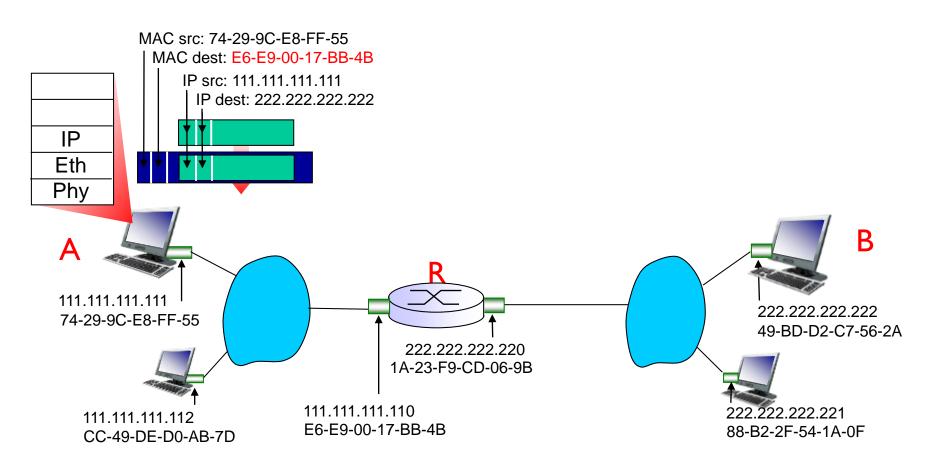

- A caches (saves) IP-to-MAC address pair in its ARP table until information becomes old (times out)
 - soft state: information that times out (goes away) unless refreshed
- ARP is "plug-and-play":
 - nodes create their ARP tables without intervention from net administrator

walkthrough: send datagram from A to B via R

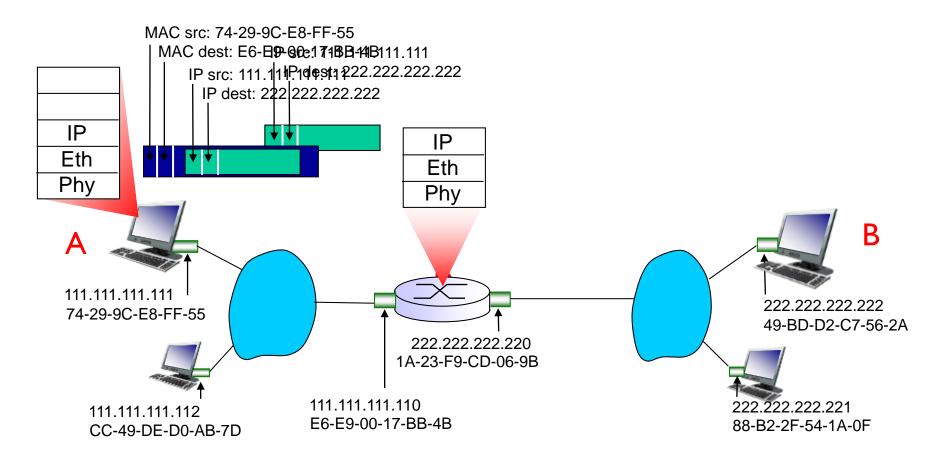

- focus on addressing at IP (datagram) and MAC layer (frame)
- assume A knows B's IP address
- assume A knows IP address of first hop router, R (how?)
- assume A knows R's MAC address (how?)

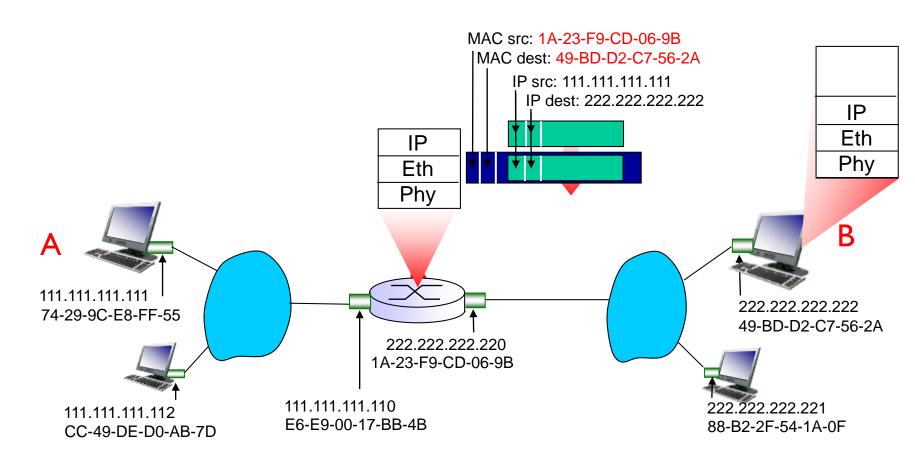

- A creates IP datagram with IP source A, destination B
- A creates link-layer frame with R's MAC address as destination address, frame contains A-to-B IP datagram

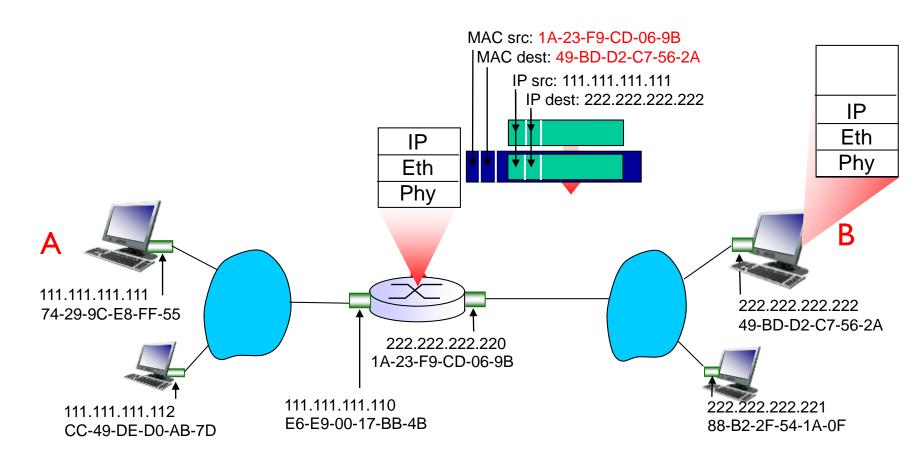

- frame sent from A to R
- frame received at R, datagram removed, passed up to IP

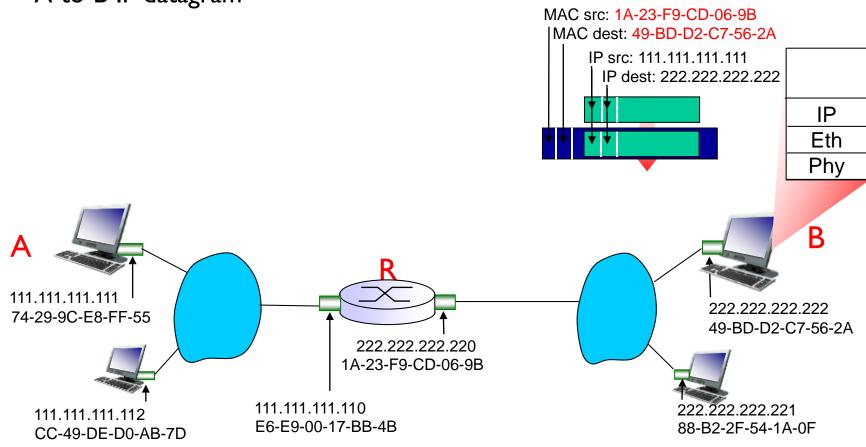

- R forwards datagram with IP source A, destination B
- R creates link-layer frame with B's MAC address as destination address, frame contains A-to-B IP datagram

- R forwards datagram with IP source A, destination B
- R creates link-layer frame with B's MAC address as destination address, frame contains A-to-B IP datagram

- R forwards datagram with IP source A, destination B
- R creates link-layer frame with B's MAC address as dest, frame contains A-to-B IP datagram

Link layer, LANs: outline

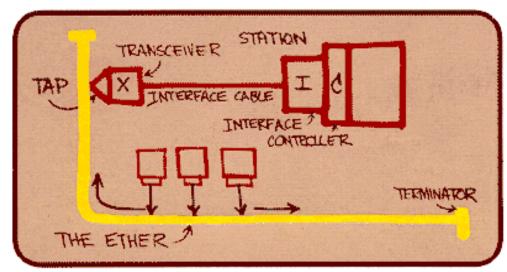

6.4 LANs

- addressing, ARP
- Ethernet
- switches
- VLANS

- 6.6 data center networking
- 6.7 a day in the life of a web request

Ethernet

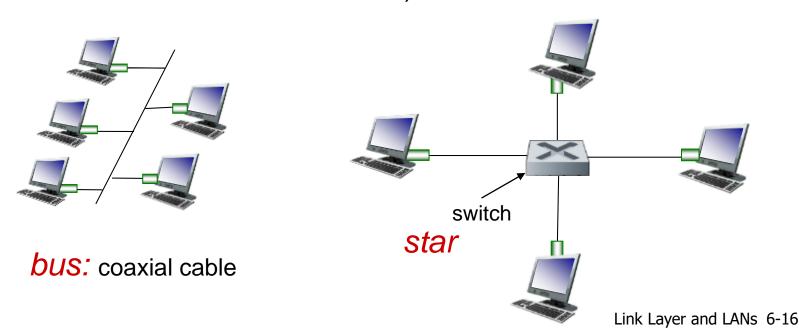

- "dominant" wired LAN technology:
- single chip, multiple speeds (e.g., Broadcom BCM5761)
- first widely used LAN technology
- simpler, cheap
- kept up with speed race: I0 Mbps I0 Gbps

Metcalfe's Ethernet sketch

Ethernet: physical topology

- bus: popular through mid 90s
 - all nodes in same collision domain (can collide with each other)
- star: prevails today
 - active switch in center
 - each "spoke" runs a (separate) Ethernet protocol (nodes do not collide with each other)

Ethernet frame structure

sending adapter encapsulates IP datagram (or other network layer protocol packet) in Ethernet frame type

preamble	dest. address	source address		data (payload)	CRC
----------	------------------	-------------------	--	-------------------	-----

preamble:

- 7 bytes with pattern 10101010 followed by one byte with pattern 10101011
- used to synchronize receiver, sender clock rates

Ethernet frame structure (more)

- addresses: 6 byte source, destination MAC addresses
 - if adapter receives frame with matching destination address, or with broadcast address (e.g. ARP packet), it passes data in frame to network layer protocol
 - otherwise, adapter discards frame
- type: indicates higher layer protocol (mostly IP but others possible, e.g., Novell IPX, AppleTalk)
- CRC: cyclic redundancy check at receiver
 - error detected: frame is dropped

Ethernet: unreliable, connectionless

- connectionless: no handshaking between sending and receiving NICs
- unreliable: receiving NIC doesn't send acks or nacks to sending NIC
 - data in dropped frames recovered only if initial sender uses higher layer rdt (e.g., TCP), otherwise dropped data lost
- Ethernet's MAC protocol: unslotted CSMA/CD with binary backoff

Link layer, LANs: outline

6.4 LANs

- addressing, ARP
- Ethernet
- switches
- VLANS

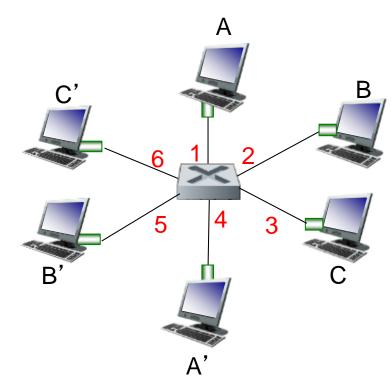

- 6.6 data center networking
- 6.7 a day in the life of a web request

Ethernet switch

- link-layer device: takes an active role
 - store, forward Ethernet frames
 - examine incoming frame's MAC address, selectively forward frame to one-or-more outgoing links when frame is to be forwarded on segment, uses CSMA/CD to access segment
- transparent
 - hosts are unaware of presence of switches
- plug-and-play, self-learning
 - switches do not need to be configured

Switch: multiple simultaneous transmissions

- hosts have dedicated, direct connection to switch
- switches buffer packets
- Ethernet protocol used on each incoming link, but no collisions; full duplex
 - each link is its own collision domain
- switching: A-to-A' and B-to-B' can transmit simultaneously, without collisions

switch with six interfaces (1,2,3,4,5,6)

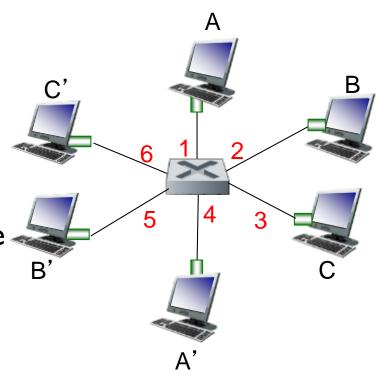

Switch forwarding table

Q: how does switch know A' reachable via interface 4, B' reachable via interface 5?

- A: each switch has a switch table, each entry:
 - (MAC address of host, interface to reach host, time stamp)
 - looks like a routing table!

Q: how are entries created, maintained in switch table?

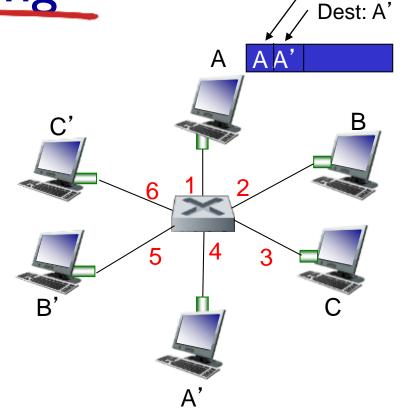

something like a routing protocol?

switch with six interfaces (1,2,3,4,5,6)

Switch: self-learning

- switch learns which hosts can be reached through which interfaces
 - when frame received, switch "learns" location of sender: incoming LAN segment
 - records sender/location pair in switch table

MAC addr	interface	TTL	
Α	1	60	

Switch table (initially empty)

Source: A

Switch: frame filtering/forwarding

when frame received at switch:

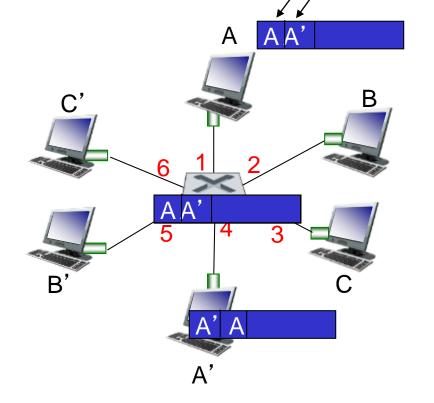

- I. record incoming link, MAC address of sending host
- 2. index switch table using MAC destination address

```
3. if entry found for destination then {
if destination on segment from which frame arrived then drop frame
else forward frame on interface indicated by entry
}
else flood /* forward on all interfaces except arriving interface */
```

Self-learning, forwarding: example

Source: A Dest: A'

- frame destination, A', location unknown: flood
- destination A location known: selectively send on just one link

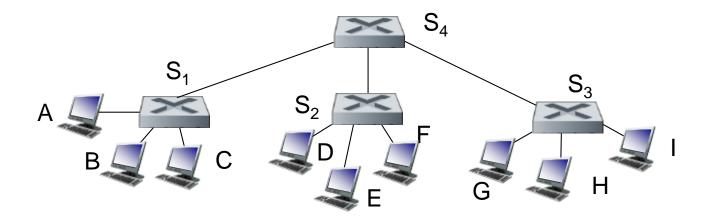

MAC addr	interface	TTL
Α	1	60
A'	4	60

switch table (initially empty)

Interconnecting switches

self-learning switches can be connected together:

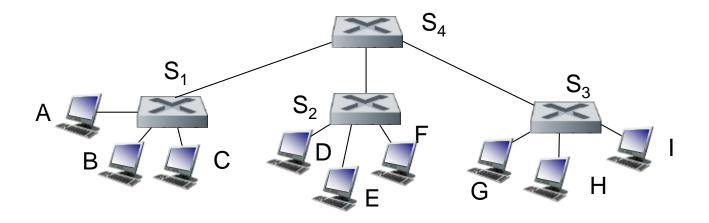

Q: sending from A to G - how does S_1 know to forward frame destined to G via S_4 and S_3 ?

A: self learning! (works exactly the same as in single-switch case!)

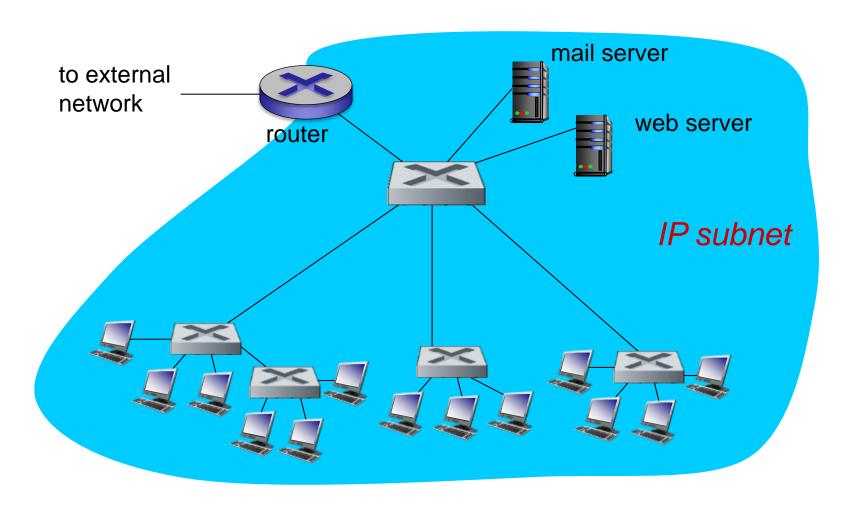

Self-learning multi-switch example

Suppose C sends frame to I, I responds to C

• Q: show switch tables and packet forwarding in S_1 , S_2 , S_3 , S_4

Institutional network

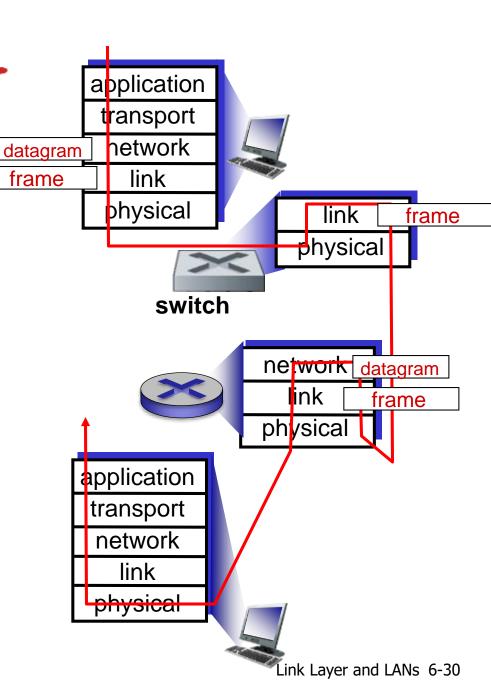

Switches vs. routers

both are store-and-forward:

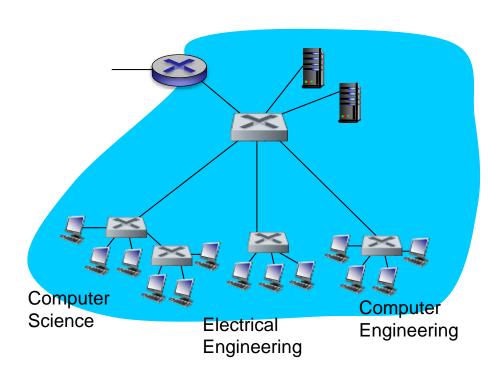

- routers: network-layer devices (examine networklayer headers)
- switches: link-layer devices (examine link-layer headers)

both have forwarding tables:

- routers: compute tables using routing algorithms, IP addresses
- switches: learn forwarding table using flooding, learning, MAC addresses

VLANs: motivation

consider:

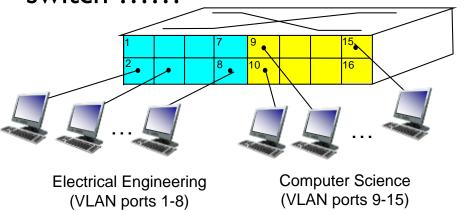

- CS user moves office to EE, but wants connect to CS switch?
- single broadcast domain:
 - all layer-2 broadcast traffic (ARP, DHCP, unknown location of destination MAC address) must cross entire LAN
 - security/privacy, efficiency issues

VLANs

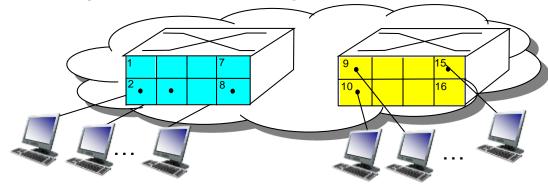

Virtual Local Area Network

switch(es) supporting VLAN capabilities can be configured to define multiple *virtual* LANS over single physical LAN infrastructure.

port-based VLAN: switch ports grouped (by switch management software) so that single physical switch

... operates as multiple virtual switches

Electrical Engineering (VLAN ports 1-8)

Computer Science (VLAN ports 9-16)

Link layer, LANs: outline

6.4 LANs

- addressing, ARP
- Ethernet
- switches
- VLANS

- 6.6 data center networking
- 6.7 a day in the life of a web request

Data center networks

- 10's to 100's of thousands of hosts, often closely coupled, in close proximity:
 - e-business (e.g. Amazon)
 - content-servers (e.g., YouTube, Akamai, Apple, Microsoft)
 - search engines, data mining (e.g., Google)

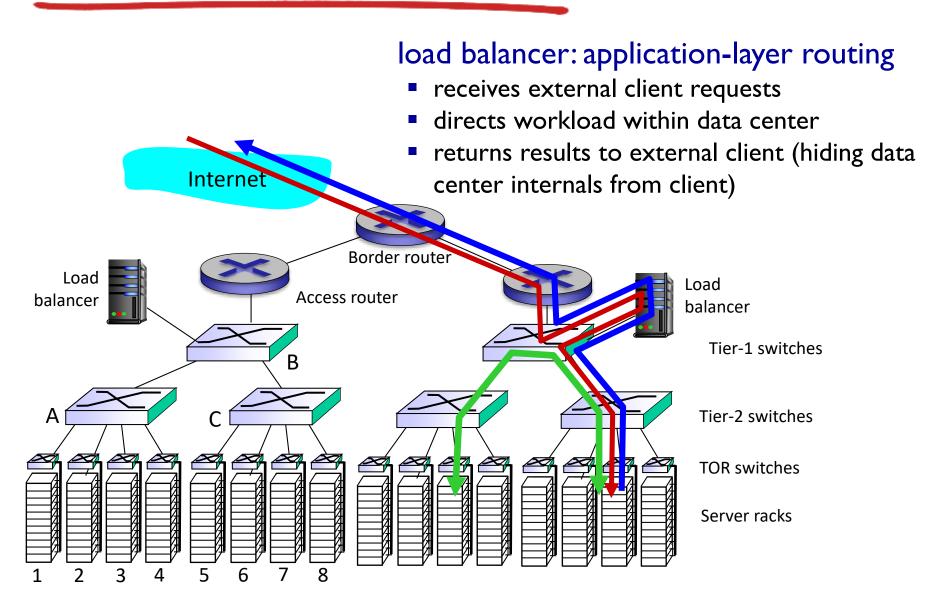

challenges:

- multiple applications, each serving massive numbers of clients
- managing/balancing load, avoiding processing, networking, data bottlenecks

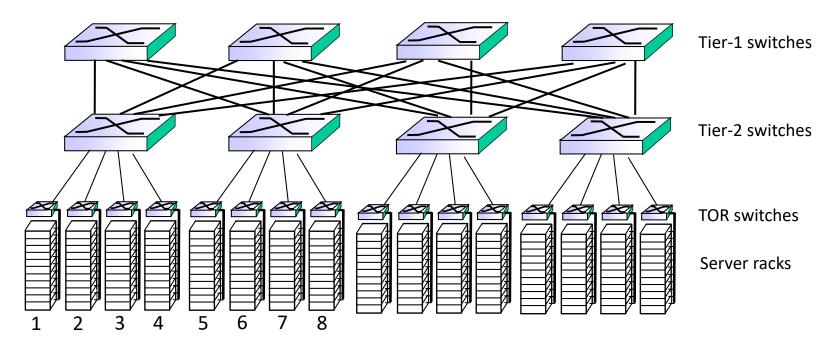

Inside a 40-ft Microsoft container, Chicago data center

Data center networks

Data center networks

- rich interconnection among switches, racks:
 - increased throughput between racks (multiple routing paths possible)
 - increased reliability via redundancy

Link layer, LANs: outline

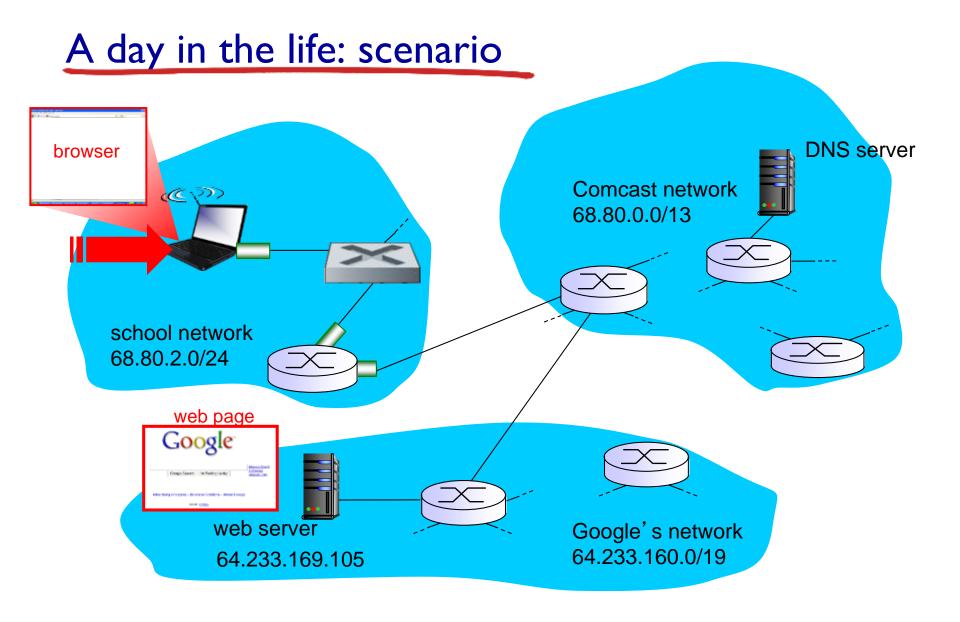

6.4 LANs

- addressing, ARP
- Ethernet
- switches
- VLANS

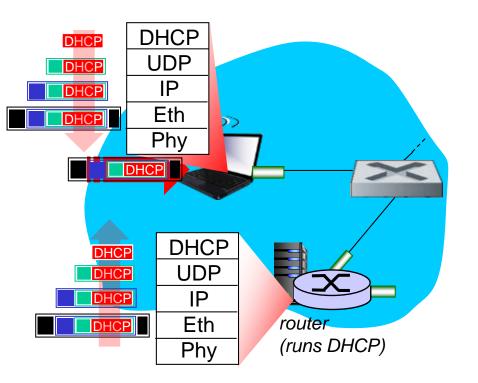

- 6.6 data center networking
- 6.7 a day in the life of a web request

Synthesis: a day in the life of a web request

- journey down protocol stack complete!
 - application, transport, network, link
- putting-it-all-together: synthesis!
 - goal: identify, review, understand protocols (at all layers) involved in seemingly simple scenario: requesting www page
 - scenario: student attaches laptop to campus network, requests/receives www.google.com

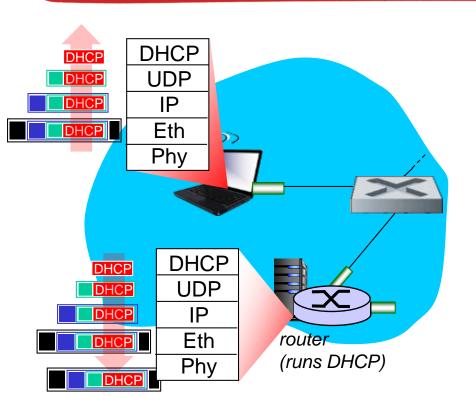

A day in the life... connecting to the Internet

- connecting laptop needs to get its own IP address, addr of first-hop router, addr of DNS server: use DHCP
- DHCP request encapsulated in UDP, encapsulated in IP, encapsulated in 802.3 Ethernet
- Ethernet frame broadcast (dest: FFFFFFFFFFFFF) on LAN, received at router running DHCP server
- Ethernet demuxed to IP demuxed, UDP demuxed to DHCP

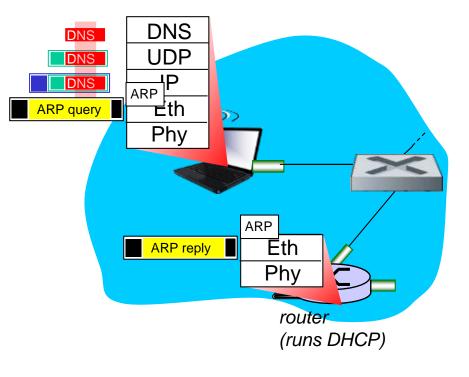

A day in the life... connecting to the Internet

- DHCP server formulates
 DHCP ACK containing
 client's IP address, IP
 address of first-hop router
 for client, name & IP address
 of DNS server
- encapsulation at DHCP server, frame forwarded (switch learning) through LAN, demultiplexing at client
- DHCP client receives DHCP ACK reply

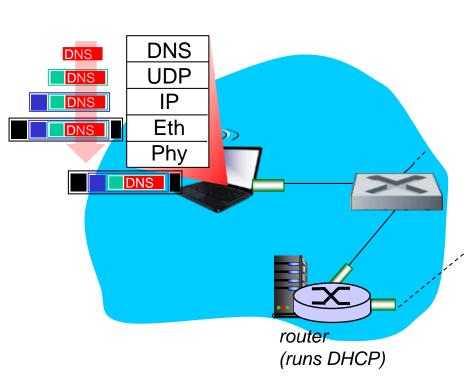

Client now has IP address, knows name & addr of DNS server, IP address of its first-hop router

A day in the life... ARP (before DNS, before HTTP)

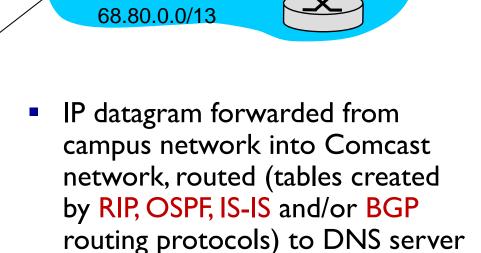

- before sending HTTP request, need IP address of www.google.com: DNS
- DNS query created, encapsulated in UDP, encapsulated in IP, encapsulated in Eth. To send frame to router, need MAC address of router interface: ARP
- ARP query broadcast, received by router, which replies with ARP reply giving MAC address of router interface
- client now knows MAC address of first hop router, so can now send frame containing DNS query

A day in the life... using DNS

 IP datagram containing DNS query forwarded via LAN switch from client to Ist hop router

demuxed to DNS server

<u>DNS</u> UDP

IΡ

Eth

Phy

Comcast network

DNS

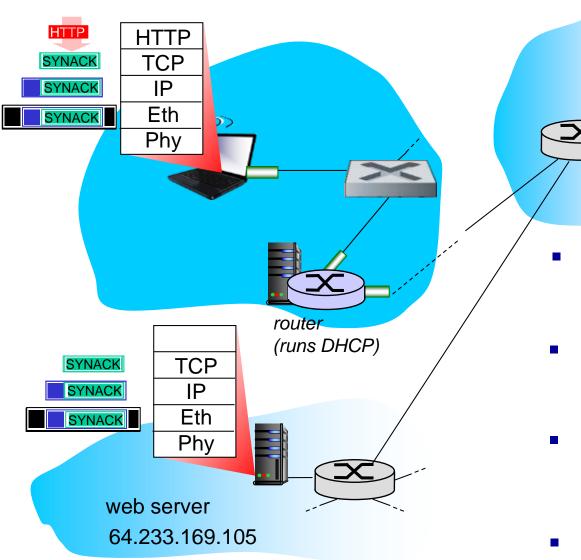

DNS

DNS

 DNS server replies to client with IP address of www.google.com

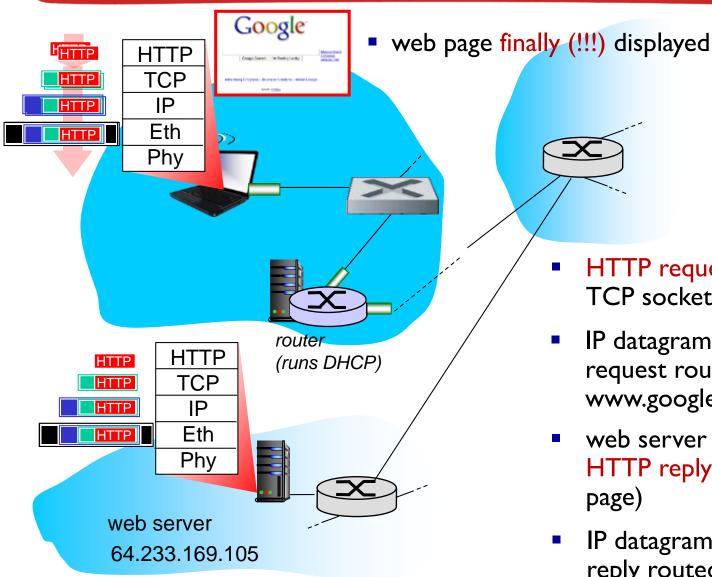

ONS server

A day in the life...TCP connection carrying HTTP

- to send HTTP request, client first opens TCP socket to web server
- TCP SYN segment (step I in 3way handshake) inter-domain routed to web server
- web server responds with TCP SYNACK (step 2 in 3-way handshake)
- TCP connection established!

A day in the life... HTTP request/reply

- HTTP request sent into TCP socket
- IP datagram containing HTTP request routed to www.google.com
- web server responds with HTTP reply (containing web page)
- IP datagram containing HTTP reply routed back to client

Chapter 6: Summary

- principles behind data link layer services:
 - error detection, correction
 - sharing a broadcast channel: multiple access
 - link layer addressing
- instantiation and implementation of various link layer technologies
 - Ethernet
 - switched LANS, VLANs
 - virtualized networks as a link layer: MPLS
- synthesis: a day in the life of a web request

Chapter 6: let's take a breath

- journey down protocol stack complete (except PHY)
- solid understanding of networking principles, practice
- could stop here but lots of interesting topics!
 - wireless
 - multimedia
 - security

Lecture 9: Review Questions

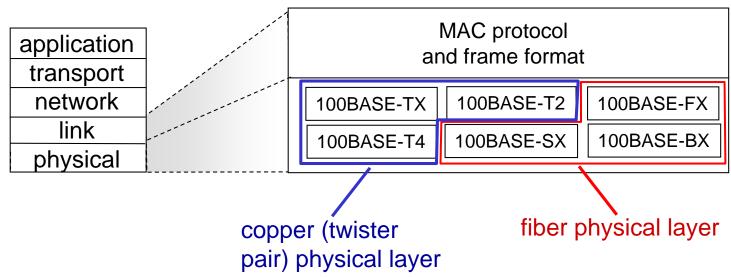

- Why is it important to have both IP and MAC addresses?
- Can an Ethernet frame contain an undetected error, and is yes, when would it be detected?
- Can a fragment cycle through a switch network, why?

Lecture 9: Extra Material

- Ethernet standards
- Some more about VLAN
- Link virtualization: MPLS

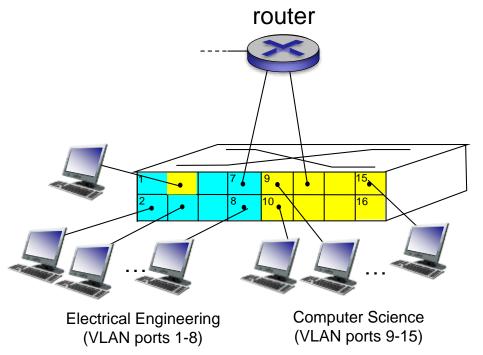

802.3 Ethernet standards: link & physical layers

- many different Ethernet standards
 - common MAC protocol and frame format
 - different speeds: 2 Mbps, 10 Mbps, 100 Mbps, 1Gbps, 10 Gbps, 40 Gbps
 - different physical layer media: fiber, cable

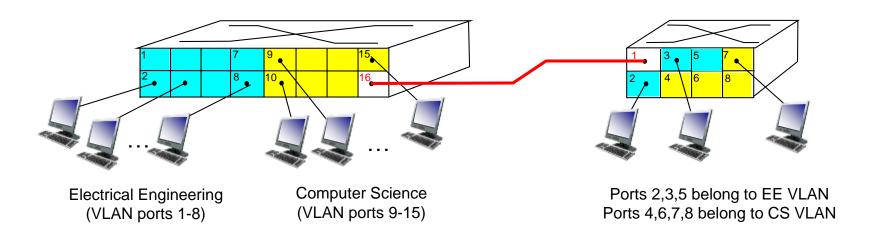

Port-based VLAN

- traffic isolation: frames to/from ports 1-8 can only reach ports 1-8
 - can also define VLAN based on MAC addresses of endpoints, rather than switch port
- dynamic membership: ports can be dynamically assigned among VLANs

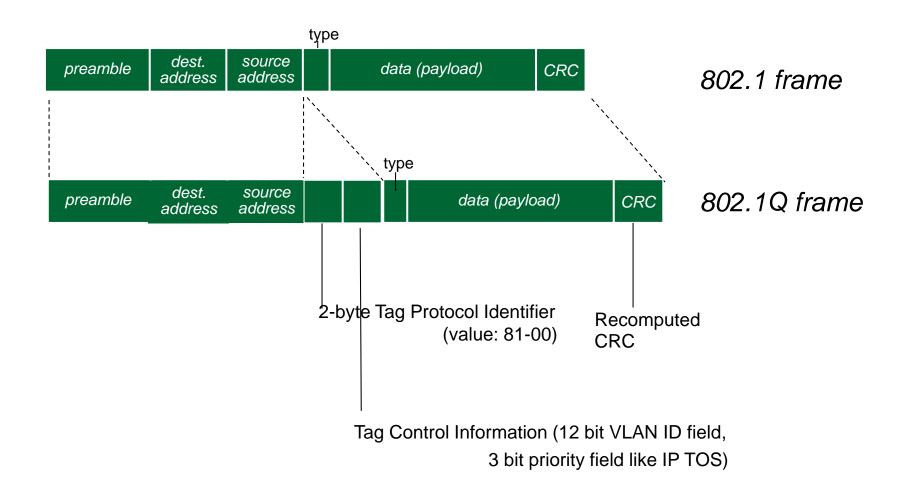

- forwarding between VLANS: done via routing (just as with separate switches)
 - in practice vendors sell combined switches plus routers

VLANS spanning multiple switches

- trunk port: carries frames between VLANS defined over multiple physical switches
 - frames forwarded within VLAN between switches can't be vanilla 802.1 frames (must carry VLAN ID info)
 - 802. I q protocol adds/removed additional header fields for frames forwarded between trunk ports

802. I Q VLAN frame format

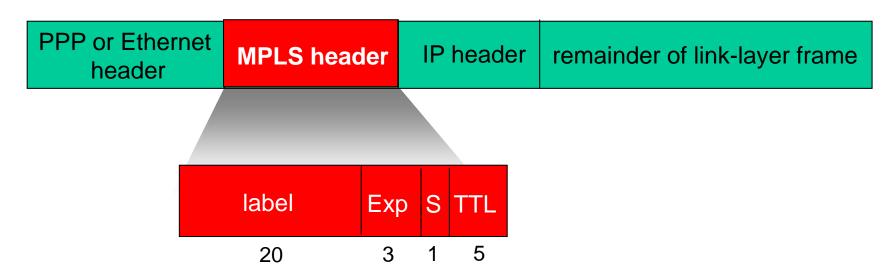

Link layer, LANs: outline

- 6. I introduction, services
- 6.2 error detection, correction
- 6.3 multiple access protocols
- 6.4 LANs
 - · addressing, ARP
 - Ethernet
 - switches
 - VLANS

- 6.5 link virtualization: MPLS
- 6.6 data center networking
- 6.7 a day in the life of a web request

Multiprotocol label switching (MPLS)

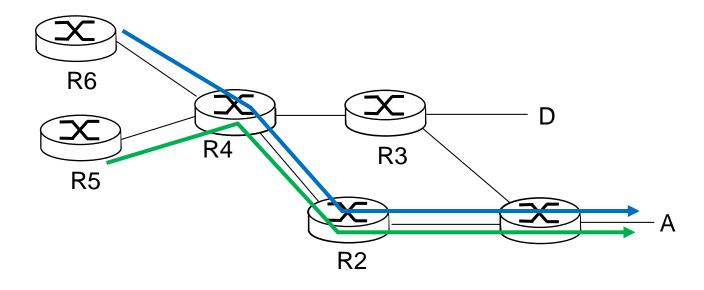

- initial goal: high-speed IP forwarding using fixed length label (instead of IP address)
 - fast lookup using fixed length identifier (rather than shortest prefix matching)
 - borrowing ideas from Virtual Circuit (VC) approach
 - but IP datagram still keeps IP address!

MPLS capable routers

- a.k.a. label-switched router
- forward packets to outgoing interface based only on label value (don't inspect IP address)
 - MPLS forwarding table distinct from IP forwarding tables
- flexibility: MPLS forwarding decisions can differ from those of IP
 - use destination and source addresses to route flows to same destination differently (traffic engineering)
 - re-route flows quickly if link fails: pre-computed backup paths (useful for VoIP)

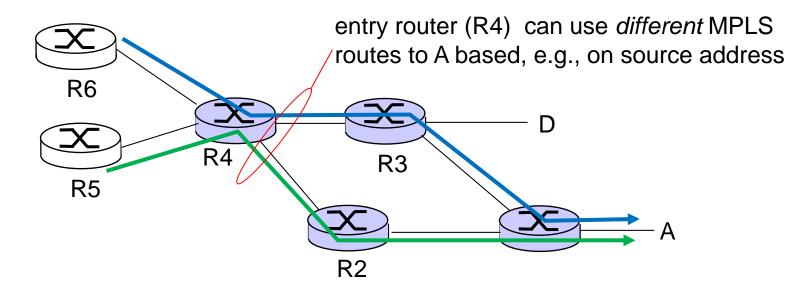

MPLS versus IP paths

 IP routing: path to destination determined by destination address alone

MPLS versus IP paths

 IP routing: path to destination determined by destination address alone

IP-only router

 MPLS routing: path to destination can be based on source and destination address

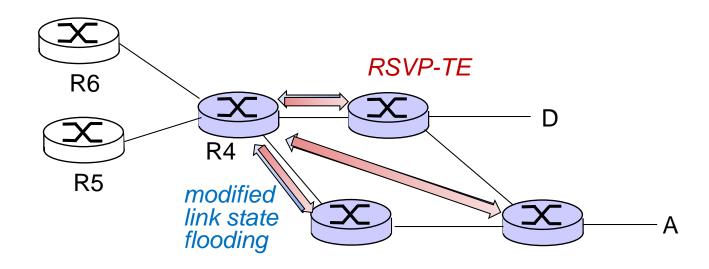

MPLS and IP router

 fast reroute: precompute backup routes in case of link failure

MPLS signaling

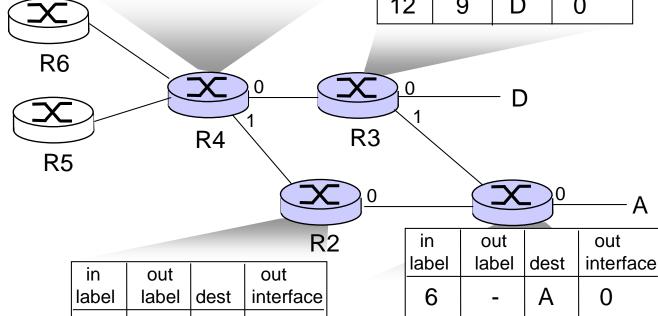

- modify OSPF, IS-IS link-state flooding protocols to carry info used by MPLS routing,
 - e.g., link bandwidth, amount of "reserved" link bandwidth
- entry MPLS router uses RSVP-TE signaling protocol to set up MPLS forwarding at downstream routers

MPLS forwarding tables

in label	out label	dest	out interface
10	6	Α	1
12	9	D	0

in	out		out
label	label	dest	interface
8	6	Α	0
