

Formal Methods for Software Development

Reasoning about Programs with Dynamic Logic

Wolfgang Ahrendt

11 October 2018

Part I

Where are we?

Where Are We?

before specification of JAVA programs with JML

now dynamic logic (DL) for reasoning about JAVA programs

after that generating DL from JML+JAVA

+ verifying the resulting proof obligations

Motivation

Consider the method

```
public void doubleContent(int[] a) {  
    int i = 0;  
    while (i < a.length) {  
        a[i] = a[i] * 2;  
        i++;  
    }  
}
```

We want a **logic/calculus** allowing to **express/prove** properties like, e.g.:

If $a \neq \text{null}$

then `doubleContent` terminates normally

and afterwards all elements of `a` are twice the old value

Dynamic Logic (Preview)

One such logic is **dynamic logic** (DL)

The above statement can be expressed in DL as follows:
(assuming a suitable signature)

$$\begin{aligned} & a \neq \text{null} \\ & \wedge a \neq \text{old_a} \\ & \wedge \forall \text{int } i; ((0 \leq i \wedge i < a.\text{length}) \rightarrow a[i] = \text{old_a}[i]) \\ \rightarrow & \langle \text{doubleContent}(a); \rangle \\ & \forall \text{int } i; ((0 \leq i \wedge i < a.\text{length}) \rightarrow a[i] = 2 * \text{old_a}[i]) \end{aligned}$$

Observations

- ▶ DL combines first-order logic (FOL) with programs
- ▶ Theory of DL extends theory of FOL

introducing **dynamic logic** for JAVA

- ▶ short recap first-order logic (FOL)
- ▶ dynamic logic = extending FOL with
 - ▶ **dynamic interpretations**
 - ▶ **programs** to describe state change

Recap: First-Order States

Definition (First-Order State)

Let \mathcal{D} be a domain with typing function δ .

For each f be declared as $\tau f(\tau_1, \dots, \tau_r)$;

and each p be declared as $p(\tau_1, \dots, \tau_r)$;

$\mathcal{I}(f)$ is a mapping $\mathcal{I}(f) : \mathcal{D}^{\tau_1} \times \dots \times \mathcal{D}^{\tau_r} \rightarrow \mathcal{D}^{\tau}$

$\mathcal{I}(p)$ is a set $\mathcal{I}(p) \subseteq \mathcal{D}^{\tau_1} \times \dots \times \mathcal{D}^{\tau_r}$

Then $\mathcal{S} = (\mathcal{D}, \delta, \mathcal{I})$ is a **first-order state**

Part II

Towards Dynamic Logic

Reasoning about Java programs requires extensions of FOL

- ▶ JAVA type hierarchy
- ▶ JAVA program variables
- ▶ JAVA heap for reference types (next lecture)

Type Hierarchy

Definition (Type Hierarchy)

- ▶ T_Σ is set of **types**
- ▶ **Subtype** relation $\sqsubseteq \subseteq T_\Sigma \times T_\Sigma$ with top element \top
 - ▶ $\tau \sqsubseteq \top$ for all $\tau \in T_\Sigma$

Example (A Minimal Type Hierarchy)

$$T_\Sigma = \{\top\}$$

All signature symbols have same type \top

Example (Type Hierarchy for Java)

(see next slide)

Modelling Java in FOL: Fixing a Type Hierarchy

Signature based on Java's type hierarchy (sketch)

Each interface and class in API and in target program becomes type with appropriate subtype relation

Subset of Types

Signature based on Java's type hierarchy

int and **boolean** are the only types for today.
Class, interfaces, arrays: next lecture.

Modelling Dynamic Properties

Only static properties expressible in typed FOL, e.g.,

- ▶ Values of fields in a certain range
- ▶ Invariant of a class implies invariant of its interface

Considers only one program state at a time

Goal: Express behavior of a program, e.g.:

If method `setAge` is called on an object `o` of type `Person`
and the method argument `newAge` is positive
then afterwards field `age` has same value as `newAge`

Requirements

Requirements for a logic to reason about programs

- ▶ Can relate different program states, i.e., **before** and **after** execution, within a single formula
- ▶ Program variables are represented by **constant symbols**, whose value **depend** on program **state**

Dynamic Logic meets the above requirements

Dynamic Logic

(JAVA) Dynamic Logic

Typed FOL

- ▶ + programs p
- ▶ + modalities $\langle p \rangle \phi$, $[p] \phi$ (p program, ϕ DL formula)
- ▶ + ... (later)

An Example

$$i > 5 \rightarrow [i = i + 10;]i > 15$$

Meaning?

If **program variable** i is greater than 5 in current state, then **after** executing the JAVA statement “ $i = i + 10;$ ”, i is greater than 15

Program Variables

Dynamic Logic = Typed FOL + ...

$$i > 5 \rightarrow [i = i + 10;]i > 15$$

Program variable i refers to different values before and after execution

- ▶ Program variables such as i are state-dependent constant symbols
- ▶ Value of state-dependent symbols changeable by a program

Three words one meaning: state-dependent, non-rigid, flexible

Rigid versus Flexible Symbols

Signature of program logic defined as in FOL, but in addition, there are **program variables**

Rigid versus Flexible

- ▶ **Rigid** symbols, meaning insensitive to program states
 - ▶ First-order variables (aka **logical variables**)
 - ▶ Built-in functions and predicates such as $0, 1, \dots, +, *, \dots, <, \dots$
- ▶ **Flexible** (or **non-rigid**) symbols, meaning depends on state. Capture side effects on state during program execution
 - ▶ **Program variables** are flexible

Any term containing at least one flexible symbol is called flexible

Signature of Dynamic Logic

Definition (Dynamic Logic Signature)

$$\Sigma = (P_\Sigma, F_\Sigma, PV_\Sigma, \alpha_\Sigma), \quad F_\Sigma \cap PV_\Sigma = \emptyset$$

(Rigid) **Predicate** Symbols $P_\Sigma = \{>, >=, \dots\}$

(Rigid) **Function** Symbols $F_\Sigma = \{+, -, *, 0, 1, \dots\}$

Flexible Program variables e.g. $PV_\Sigma = \{i, j, \text{ready}, \dots\}$

Standard typing of JAVA symbols: `boolean TRUE; <(int,int); ...`

Dynamic Logic Signature - KeY input file

```
\sorts {  
  // only additional sorts (int, boolean, any predefined)  
}  
\functions {  
  // only additional rigid functions  
  // (arithmetic functions like +,- etc., predefined)  
}  
\predicates { /* same as for functions */ }  
  
\programVariables { // flexible  
  int i, j;  
  boolean ready;  
}
```

Empty sections can be left out

Again: Two Kinds of Variables

Rigid:

Definition (First-Order/Logical Variables)

Typed **logical variables** (**rigid**), declared locally in **quantifiers** as $\exists x;$
They must not occur in programs!

Flexible:

Program Variables

- ▶ Are **not** FO variables
- ▶ **Cannot** be quantified
- ▶ May occur in programs (and formulas)

Dynamic Logic Programs

Dynamic Logic = Typed FOL + programs ...

Programs here: any legal sequence of JAVA statements.

Example

Signature for PV_{Σ} : int r; int i; int n;

Signature for F_{Σ} : int 0; int +(int,int); int -(int,int);

Signature for P_{Σ} : <(int,int);

```
i=0;
r=0;
while (i<n) {
  i=i+1;
  r=r+i;
}
r=r+r-n;
```

Which value does the program compute in r?

Relating Program States: Modalities

DL extends FOL with two additional operators:

- ▶ $\langle p \rangle \phi$ (diamond)
- ▶ $[p] \phi$ (box)

with p a program, ϕ another DL formula

Intuitive Meaning

- ▶ $\langle p \rangle \phi$: p terminates **and** formula ϕ holds in final state
(total correctness)
- ▶ $[p] \phi$: **If** p terminates **then** formula ϕ holds in final state
(partial correctness)

Attention: JAVA programs are deterministic, i.e., **if** a JAVA program terminates then exactly **one** state is reached from a given initial state.

Dynamic Logic - Examples

Let i , j , old_i , old_j denote program variables.
Give the meaning in natural language:

1. $i = old_i \rightarrow \langle i = i + 1; \rangle i > old_i$

If $i = i + 1$; is executed in a state where i and old_i have the same value, then the program terminates and in its final state the value of i is greater than the value of old_i .

2. $i = old_i \rightarrow [\text{while}(\text{true})\{i = old_i - 1;\}] i > old_i$

If the program is executed in a state where i and old_i have the same value and if the program terminates then in its final state the value of i is greater than the value of old_i .

3. $\forall x. (\langle prog_1 \rangle i = x \leftrightarrow \langle prog_2 \rangle i = x)$

$prog_1$ and $prog_2$ are equivalent concerning termination and the final value of i .

Dynamic Logic: KeY Input File

```
\programVariables { // Declares global program variables
  int i;
  int old_i;
}
```

```
\problem { // The problem to verify is stated here
  i = old_i -> \<{ i = i + 1; }\> i > old_i
}
```

Visibility

- ▶ Program variables declared globally can be accessed anywhere
- ▶ Program variables declared inside a modality only visible therein.
E.g., in “ $pre \rightarrow \langle \mathbf{int} \ j; \ p \rangle post$ ”, j not visible in $post$

Dynamic Logic Formulas

Definition (Dynamic Logic Formulas (DL Formulas))

- ▶ Each FOL formula is a DL formula
 - ▶ If p is a program and ϕ a DL formula, then $\left\{ \begin{array}{l} \langle p \rangle \phi \\ [p] \phi \end{array} \right\}$ is a DL formula
 - ▶ DL formulas closed under FOL quantifiers and connectives
-
- ▶ Program variables are **flexible constants**: never bound in quantifiers
 - ▶ Program variables need not be declared or initialized in program
 - ▶ Programs contain no logical variables
 - ▶ Modalities can be arbitrarily nested, e.g., $\langle p \rangle [q] \phi$

Example (Well-formed? If yes, under which signature?)

- ▶ $\forall \text{int } y; ((\langle x = 2; \rangle x = y) \leftrightarrow (\langle x = 1; x++; \rangle x = y))$
Well-formed if PV_{Σ} contains $\text{int } x$;
- ▶ $\exists \text{int } x; [x = 1;](x = 1)$
Not well-formed, because logical variable occurs in program
- ▶ $\langle x = 1; \rangle ([\text{while } (\text{true}) \{ \}] \text{false})$
Well-formed if PV_{Σ} contains $\text{int } x$;
program formulas can be nested

Dynamic Logic Semantics: States

First-order state can be considered as **program state**

- ▶ Interpretation of (flexible) program variables can vary from state to state
- ▶ Interpretation of **rigid** symbols is the same in all states (e.g., built-in functions and predicates)

Program states as first-order states

We identify **first-order state** $\mathcal{S} = (\mathcal{D}, \delta, \mathcal{I})$ with **program state**.

- ▶ Interpretation \mathcal{I} only changes on program variables.
⇒ Enough to record values of variables $\in PV_{\Sigma}$
- ▶ Set of all states \mathcal{S} is called *States*

Kripke Structure

Definition (Kripke Structure)

Kripke Structure or **Labelled Transition System** $K = (States, \rho)$

- ▶ **States** $\mathcal{S} = (\mathcal{D}, \delta, \mathcal{I}) \in States$
- ▶ **Transition relation** $\rho : Program \rightarrow (States \rightarrow States)$

$$\rho(p)(\mathcal{S}_1) = \mathcal{S}_2$$

iff.

program p executed in state \mathcal{S}_1 terminates **and** its final state is \mathcal{S}_2 ,
otherwise undefined.

- ▶ ρ is the **semantics** of programs $\in Program$
- ▶ $\rho(p)(\mathcal{S})$ can be undefined (' \rightarrow '): p may **not terminate** when started in \mathcal{S}
- ▶ JAVA programs are **deterministic** (unlike PROMELA): $\rho(p)$ is a function (at most one value)

Semantic Evaluation of Program Formulas

Definition (Validity Relation for Program Formulas)

- ▶ $\mathcal{S} \models \langle p \rangle \phi$ iff $\rho(p)(\mathcal{S})$ is defined and $\rho(p)(\mathcal{S}) \models \phi$
(p terminates and ϕ is true in the final state after execution)
- ▶ $s \models [p]\phi$ iff $\rho(p)(\mathcal{S}) \models \phi$ whenever $\rho(p)(\mathcal{S})$ is defined
(If p terminates then ϕ is true in the final state after execution)

A DL formula ϕ is **valid** iff $\mathcal{S} \models \phi$ for all states \mathcal{S} .

- ▶ **Duality:** $\langle p \rangle \phi$ iff $\neg[p]\neg\phi$
Exercise: justify this with help of semantic definitions
- ▶ **Implication:** if $\langle p \rangle \phi$ then $[p]\phi$
Total correctness implies partial correctness
 - ▶ converse is false
 - ▶ holds only for deterministic programs

More Examples

Meaning?

Example

$$\forall \tau y; ((\langle p \rangle x = y) \leftrightarrow (\langle q \rangle x = y))$$

Programs p and q behave equivalently on variable τx .

Example

$$\exists \tau y; (x = y \rightarrow \langle p \rangle \text{true})$$

Program p terminates if initial value of x is suitably chosen.

Semantics of Programs

In labelled transition system $K = (\text{States}, \rho)$:
 $\rho : \text{Program} \rightarrow (\text{States} \rightarrow \text{States})$ is **semantics** of programs $p \in \text{Program}$

ρ defined recursively on programs

Example (Semantics of assignment)

States \mathcal{S} interpret program variables v with $\mathcal{I}_{\mathcal{S}}(v)$

$$\rho(x=t;)(\mathcal{S}) = \mathcal{S}' \quad \text{where} \quad \mathcal{I}_{\mathcal{S}'}(y) := \begin{cases} \mathcal{I}_{\mathcal{S}}(y) & y \neq x \\ \text{val}_{\mathcal{S}}(t) & y = x \end{cases}$$

Very advanced task to define ρ for JAVA \Rightarrow Not done in this course
Next lecture, we go directly to calculus for program formulas!
